# EXECUTIVE SUMMARY

From November 3, 1994 to January 12, 1995 a team of Bechtel and PTS radiological safety specialists conducted a survey to characterize the radiological levels and distribution over the surface of Potential Source of Contamination Number 26 (PSC 26) at the Jacksonville Naval Air Station (NAS) Jacksonville, Florida. The principal radiological contaminant had been previously determined to be radium-226, used in the 1940-1950s time frame as a luminous dial marker for aircraft instrumentation. The radium-226 contamination resulted from operation of an instrument repair and maintenance operation on the base that utilized the luminous paint as part of the facility operations.

The radiation survey consisted of a 100 percent walkover gamma survey to locate elevated activity in excess of twice the background. These elevated locations (hot spots) were then characterized to determine radiation level and size as well as location within the pre-established grid system on the site. Radiation levels were determined at the point of highest reading and consisted of beta, gamma, alpha, and dose rate readings. The size of the elevated reading was defined by the four compass points at which the gamma reading fell to 20 percent above background. The hot spot characterization was supplemented by recording the average gamma dose rate reading at each grid intersection point to provide a general gamma profile over the site. Sediment samples were taken in the moat surrounding the site and soil samples were taken on the site at selected hot spot locations, chosen to be representative of areal extent and level of activity encountered over the site.

The characterization identified a total of 169 hot spots over the 38 acre site that exceeded the twice background designation criteria. These hot spots were found to vary in size from several feet in diameter to areas as large as a total grid (150 ft by 150 ft). Levels of activity were as high as 500 μR/hr. The average background at the grid intersections onsite is approximately 5μR/hr within several centimeters of the surface. Several of the hot spots were removed and identified as electrical components. More detailed characterization determined that these components contained 2-3 μCi of radium-226. Applying this source level to the field characterization surface readings that ranged between twice background and the maximum observation of 500 μR/hr would infer, from radiation attenuation in soil, a distribution of components from 0 to 30 centimeters beneath the surface. Radioisotope concentrations in the sediment samples from the peripheral moat were in all cases below the levels for regulatory control.

# 1.0 INTRODUCTION

The U.S. Department of Navy, Southern Division, Naval Facilities Engineering Command intends to conduct radiological remedial actions at the Naval Air Station (NAS) Jacksonville, Florida, site in compliance with federal regulations. Prior to these activities, a Remedial Investigation/Feasibility Study (RI/FS) must be conducted to support the decision-making process for evaluating remedial action alternatives. Radiological characterization information is necessary to prepare the Remedial Investigation report.

Eighteen of the 45 specific areas within the NAS (Figure 1-1) have been identified as radiological potential sources of contamination (PSCs). Of these areas, PSC 26, an approximate 38-acre area, has been designated as a first priority for radiological remedial action. Detailed radiological surveillance of PSC 26 is required to determine the extent and magnitude of radioactive contamination remaining onsite for design of appropriate remedial actions. The radiological characterization entailed determination of the natural background radiation level and identification of contaminants at the NAS site and investigation of specific elevated radiation zones on PSC 26.

Bechtel Environmental, Inc. (BEI), the Environmental Response Action Contractor, performed these radiological characterizations in support of the remedial investigation being performed by ABB-Environmental Services, Inc. (ABB-ES).

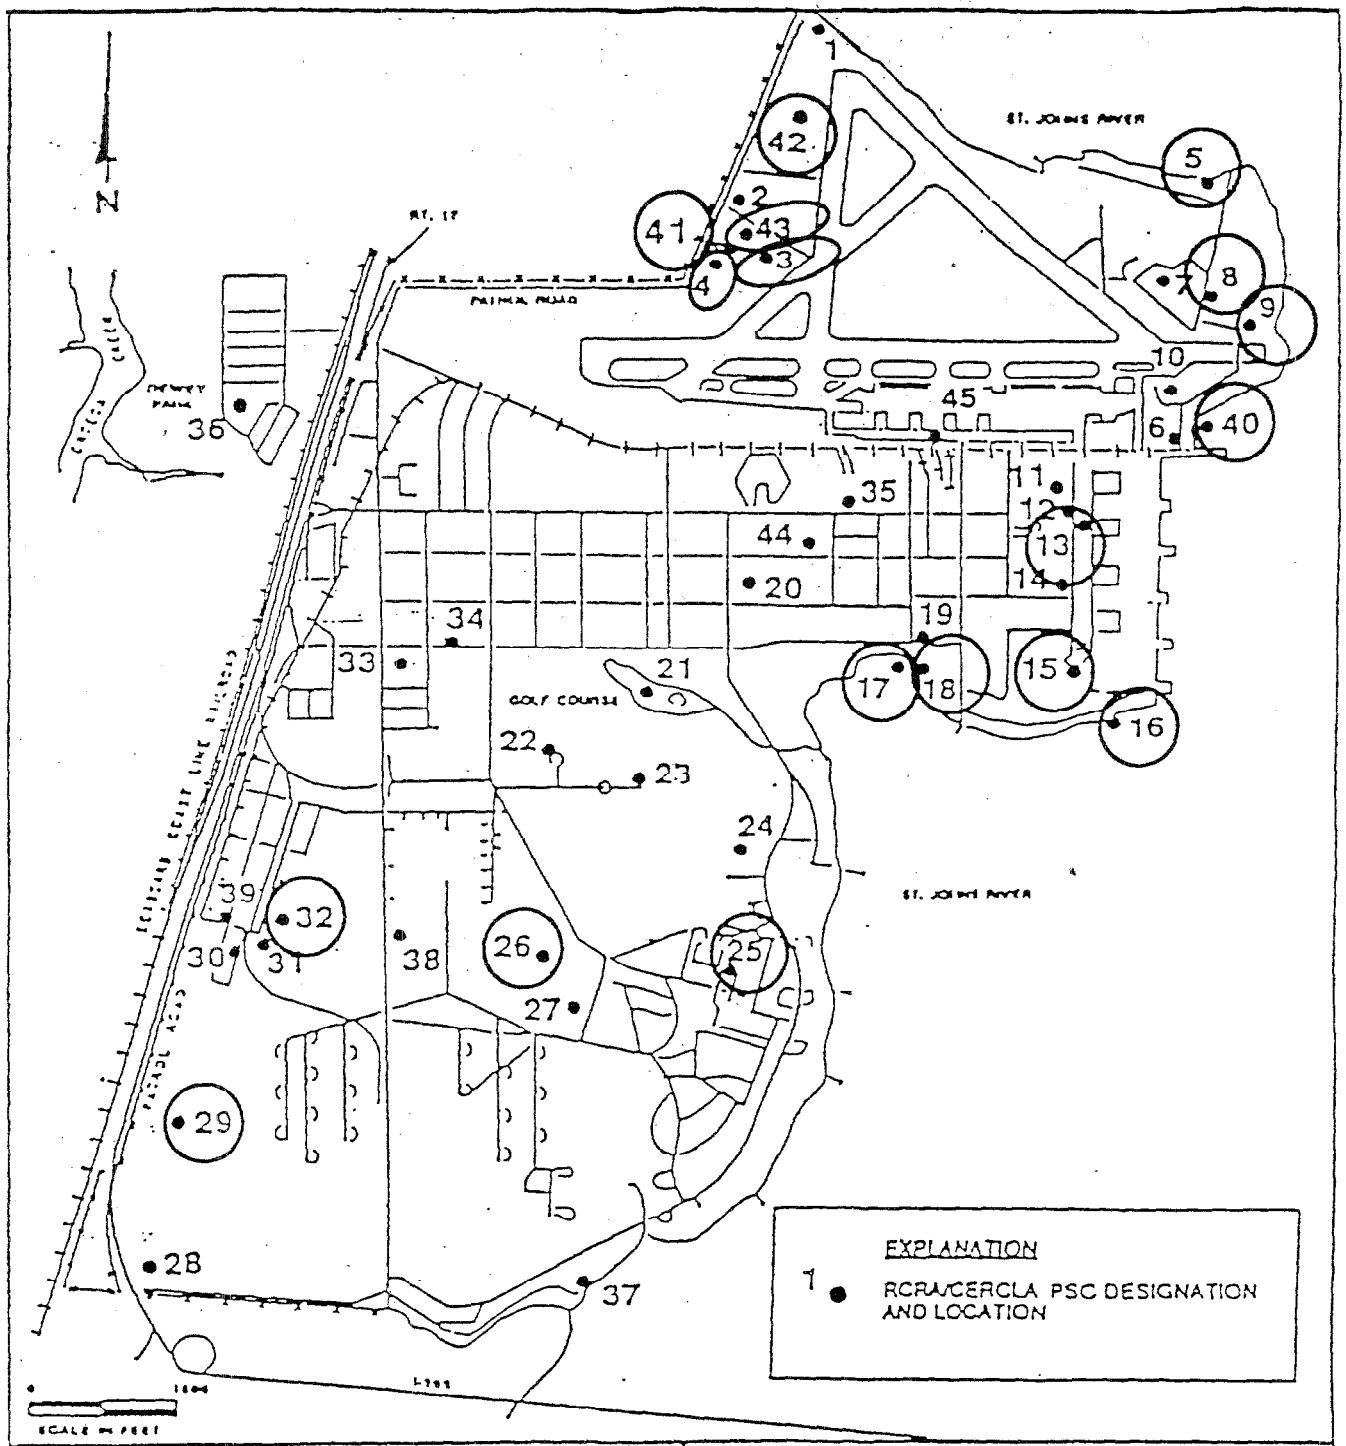
# 2.0 SITE HISTORY

The NAS Jacksonville site was originally designed for seaplane support, and when established in 1940, included facilities for pilot training and a Naval Aviation Trades School. At the end of World War II, NAS Jacksonville was devoted entirely to aviation training. The Naval Aviation Depot (NADEP) has been a major tenant of NAS Jacksonville since it operated as an assembly and repair department in 1940. The NADEP provides maintenance, engineering, logistic, and support services and performs rework, repair, and modification of aircraft, engines, and aeronautical components. Today, the NADEP is the largest tenant command on NAS Jacksonville and the largest industrial employer in Northeast Florida and Southeast Georgia, with a civilian work force of over 3,300 employees.

From June 28 to July 2, 1982, the onsite phase of a preliminary assessment (PA) was conducted as the first phase of the Naval Assessment and Control of Installation Pollutants program. This program has now been incorporated into the Navy and Marine Corps Installation Restoration (MCIR) program. The purpose of the PA was to identify, assess, and control environmental contamination from past hazardous materials storage, transfer, processing, and disposal operations. The PA identified 38 PSCs, of which 10 posed a potential threat to human health and the environment based on their Confirmation Study Ranking System (CSRS) scores. Two PSCs (PSCs 26 and 27) required interim remedial actions before conclusion of the PA.

## 2.1 PSC 26 - TERRAIN

PSC 26 is an approximate 38-acre area located near the southern midsection of the NAS site just to the west of Childs Street (Figure 2-1). This area is essentially flat terrain and contains a



PSC Locations
Figure 1-1

RI/FS WORK PLAN

Figure 2-1
PSC - 26 Area with Survey Grid

peripheral moat that encompasses about 25 acres of both cleared and forested landscape. It is estimated that about 40 percent of the PSC 26 terrain is forested and the cleared areas are covered with heavy grass. The moat width varies from approximately 10 to 20 ft, is about 3 ft deep, and contains a variety of aquatic vegetation. The moat is essentially a stagnant stream fed by the runoff from precipitation. During periods of heavy rainfall, the moat has been observed to increase in depth and run off into surrounding low lands. At several locations in its length, the moat has been dammed to permit development of roadways and also to prevent flow into other adjacent areas.

## 2.2 POTENTIAL REMEDIATION SOURCES

Several PSCs have been identified as having been potentially exposed to sources of low-level radioactive material or radioactive contamination over the past 50 years. Sources of low-level ionizing radiation in the form of luminous instrument dials are known to have been used at the site. Radium-226 was used as the source of luninesence in the dials. Several of the facilities at NAS Jacksonville were used to maintain, repair, store, or calibrate these gauges and dials.

PSC 26 is the main registered disposal area. This area was used for the disposal of a variety of wastes, including spent solvents, spent fuels, radium-painted luminous aircraft instrument dials, and low radiation level radium paint wastes. Vacuum tubes and other instrument parts with ionizing radiation sources may also have been disposed of on this site.

Many of the wastes were treated onsite by the Navy by burning. Demolition and construction debris as well as solid wastes were dumped at the edge of trenches and pits. Disposal was completed by bulldozing the remains into the trenches and pits, followed by the placement of an overburden. These disposal operations began in 1940 and continued until 1968. Air pollution controls ended the burning operations, and the solid wastes were disposed of offsite by a contractor. PSC 26 was officially closed on January 15, 1979.

## 2.3 PREVIOUS CLEANUP EFFORTS

A removal action for buried radium-painted aircraft instrument dials was conducted by the Navy on PSC 26 in the late 1950s. Over 500 55-gallon drums of contaminated soil and paint sources were cleaned up as a result of this effort and PSC 26 was released from radiological controls and returned to service after a verification survey.

In January 1993, through spot surveys, the Radiological Affairs Support Office (RASO) discovered that additional sources of radioactive material may still be buried at PSC 26. Additional areas throughout NAS Jacksonville were also identified by RASO as needing a formal radiological survey to evaluate whether additional sources of radioactive contamination exist.

## 3.0 RADIATION SURVEY PLAN

PSC 26 has been designated as a suspect area with possible residual radioactivity above background levels attributable to prior operations at NAS. Radiological remediation of this area has been assigned a first priority status, thereby necessitating the implementation of an accelerated survey plan. BEI developed a radiological survey plan that provides for radiation monitoring of 100 percent of the surface area of PSC 26 to identify areas exhibiting radiation levels that may be in excess of accepted cleanup standards. This plan also provides for the identification of radioisotopic concentrations in soil and sediment samples from PSC 26 through analytical investigations to assist in the design of remedial actions. The baseline for determining the significance of elevated radiation readings was derived from background radiological assessments in and around the NAS site. The radiological cleanup standard to be applied at NAS Jacksonville is 5 pCi/gm above background for radium-226 in soil. This will be confirmed by in situ surface measurements and surface soil samples on remediated surfaces.

### 3.1 PSC 26 PREPARATION

In order that a systematic method of radiation surveying could be employed and a convenient process of location identification be established, it was necessary to develop a grid system on PSC 26 from which work efforts and study findings could be related. The entire 38 acres of PSC 26 were surveyed and marked into a 150-ft grid pattern by a licensed civil survey subcontractor. This grid, shown in Figure 2-1, was located to a Florida State benchmark that ties it to the state grid system. As the grid was established, stakes with the proper identification notation were positioned at each grid intersection, thereby providing appropriate markers to assist the radiation survey operation. At grid intersect locations where stakes could not be positioned, as in the peripheral moat, offset stakes were positioned that identified their exact locations. Each grid intersect was assigned an identification number that assisted data collection and provided markers to which specific findings could be located.

The performance of walkover radiation surveys of the entire PSC 26 area required that its surface be cleared of shrubs, trees, and grass to a height no greater than 2 in. The areas covered with grass, small shrubs, and bushes were cut to an acceptable length using a farm tractor equipped with a bush hog. This included approximately 23 acres. About 15 acres of the 38 gridded acres were covered with very thick forest and required the services of a landscape subcontractor for removal. In this effort, all trees with trunks less than 5 in. in diameter were removed and all undergrowth was cut at ground level. The performance of radiation survey operations and landscape clearing was systematically scheduled so that clearing operations resulted in a minimum inpact on the survey efforts.

### 3.2 RADIOLOGICAL CHARACTERIZATION PROTOCOLS

The primary purpose for radiologically characterizing PSC 26 was to determine its radiological conditions compared to the NAS site and identify the extent and magnitude of radioactive contaminants and sources that were excluded in previous cleanup efforts. The information from these studies will be used in future decisions pertaining to the design of remedial action for PSC 26.

### 3.2.1 Methods of Detection

The detection of radiation-emitting sources and contaminants is normally achieved through either direct reading surveys with appropriate radiation detection instruments or by analytically determining radioisotopic concentrations in media using specific laboratory protocols. The methods used for characterizing PSC 26 involved both of these processes.

#### 3.2.1.1 Direct radiation reading surveys

Four specific direct reading survey operations were performed that accurately defined the radiological conditions of PSC 26. Initially, a 100 percent walkover gamma survey was conducted using a 2"x2" sodium iodide (NaI) detector to identify locations where radiation levels exceeded twice the background levels. In this survey, general area radiation levels were noted and "hot spots" were located, identified, and marked. The second survey involved the detailed characterization of hot spots by defining their radiological contours and measuring their peak radiation emissions. The measurements included gamma emissions, using a 2"x 2" NaI detector; gamma dose rates, using a μR meter; beta emissions, using a thin window pancake GM detector; and alpha emissions, using a zinc sulfide (ZnS) alpha scintillator detector. The description of the instruments used is summarized in Table 3-1. A third survey consisted of direct gamma emission and gamma dose rates near ground surface at each grid intersect location to characterize the average radiation status of PSC 26. A final survey was performed consisting of gamma dose rate measurements one meter above the surface at five random grid intersects using a highly accurate pressurized ion chamber (PIC) detector. Results of these surveys are discussed in Section 6.

#### 3.2.1.2 Analytical investigations

Radiation detection on PSC 26 was only intended to identify areas of elevated radiation emission and determine normal conditions and was not intended to develop detailed characterization of site media. Therefore, soil sampling and analytical study was limited to obtaining radiation information for areas where direct surveying was not possible (i.e., in the peripheral moat) and for identifying the radioisotopes present in the media of several hot spots.

An investigation of possible contaminants in the peripheral moat was performed by collecting eight sediment samples ( and one duplicate) at specific areas where contamination may be suspected (i.e., locations where excessive surface runoff into the moat may have occurred) and from random moat locations. These sediment samples were collected by standard techniques using protocols for collection, handling, and shipping that are in accordance with the Florida Department of Environmental Protection Regulation. Analyses for radioisotopic concentrations were performed using gamma spectroscopy and total uranium analytical methods.

Three soil samples from randomly selected hot spots were also collected to permit study of radioisotopic concentrations in these areas. In each case, a radioactive device was removed from a hot spot area, radioactive surveys were performed of the underlying soil, and soil samples were collected. These studies were intended to identify whether contaminants from the devices

Table 3-1
Portable Survey Instruments

| Activity | Detector type | Model | Readout |
|---|---|---|---|
| Dose rate | pressurized ion chamber | Reuter-Stokes | μR/hr |
| Dose rate | 1" by 1" NaI detector | Ludlum 19 | μR/hr |
| Gamma flux | 2" by 2" NaI detector | Ludlum 44-10 | cpm |
| Beta flux | thin window pancake GM detector | Ludlum 44-9 | cpm |
| Alpha flux | ZnS (Ag) alpha scintillator | Ludlum 43-65 | cpm |

migrated into the soil during the period of exposure. The information developed in these studies may also provide an order-of-magnitude comparison of radioisotopic concentrations with direct radiation readings.

### 3.2.2 Methods of Operation

The performance of 100 percent walkover radiation surveys of large land areas required the implementation of operational methods that ensure total survey coverage and thorough collection of relevant data. The radiation surveys on PSC 26 were performed using the 150 ft by 150 ft grid pattern that had been established to organize the survey methodology and to identify exact locations of findings. Initially, each grid section was assigned a specific number to assist worker operations and provide a simple system for data collection.

Since survey efforts were initiated prior to forest removal operations, only those grids on which surface vegetation could readily be cut to less than 2 in. in height were initially involved. Survey operations were conducted by radiation workers equipped with NaI detectors and gamma count meters following a prescribed method of monitoring. The instrument workers walked a specific pattern on each grid area accompanied by a helper who recorded data, mapped surface features, marked hot spot locations, and obtained supportive radiation measurements.

The survey method involved starting at a corner of the grid to be surveyed. The NaI detector was moved from side to side while walking at a pace of about 2 ft per second. The detector was swung in a serpentine pattern approximately 3 ft in width at a height of approximately 2 in. above the ground surface. In using this procedure, the detection capability of the radiation instruments provided a high probability for the detection of elevated gamma radiation emissions. Upon reaching the adjacent grid intersect location, the instrument worker would move sideways 3 ft and reverse his direction of travel so as to return directly to the grid line of origination. To insure parallel coverage and alignment, traffic cones connected by string were used to define the survey path. The radiation surveys performed on the grids of PSC 26 were normally conducted in the north-south direction. This process was repeated until the entire area of each grid had been surveyed.

During the performance of these surveys, area locations that exhibited elevated gamma emissions (hot spots) greater than 2 times the background radiation level, established as part of the daily source check for each NaI detector, were marked with flags and assigned specific identification numbers. The gamma radiation levels for these locations were noted on data sheets and detailed characterization surveys were conducted at a later date. Each hot spot was precisely located by measuring its distance from the southeast interval of the grid within which it was present. These measurements were recorded as *x,y* coordinates.

Hot spot characterization involved developing a radiation contour by defining the boundaries that exhibited radiation levels 20 percent higher than background levels and precisely locating the point within each hot spot with the peak gamma, beta, and alpha radiation levels. Separate data sheets for the hot spot information were generated to emphasize the size and radiation features of the various hot spots.

The normal background radiation characteristic of PSC 26 was studied by performing gamma radiation measurements at each of the 116 grid intersect locations. The intent of this survey was to identify the range of the local "apparent" background across the site. Since two of the grid intersect locations were underwater, only 114 of the positions were surveyed. The surveys included measurement of the gamma count rate for one full minute accompanied by measurement of the gamma dose rate. These studies were supplemented by a series of dose rate measurements at five random grid intersect locations using a PIC instrument to confirm the μR meter readings. Parallel PIC and μR meter readings were taken approximately one meter above the surface.. The PIC is recognized as the most reliable and accurate instrument for performing near background in situ gamma dose rate measurements. However, because of its size, configuration, and fragility, it is not a practical portable instrument for field use. It was used in these studies to obtain correlations for the dose rate readings from the different instruments used in this characterization.

After the forested areas were cleared, the radiation survey process was continued until all of the required locations on PSC 26 were complete. Additionally, temporary structures (tenting) that existed on some of the grid areas were removed, and the areas cleared and surveyed. These structures were repositioned upon completion of the survey work.

## 4.0 BACKGROUND DETERMINATION

### 4.1 INTRODUCTION

The operating history of the NAS Jacksonville site has included handling and disposal of materials containing low levels of radioactive materials. Onsite activities involving such materials included:

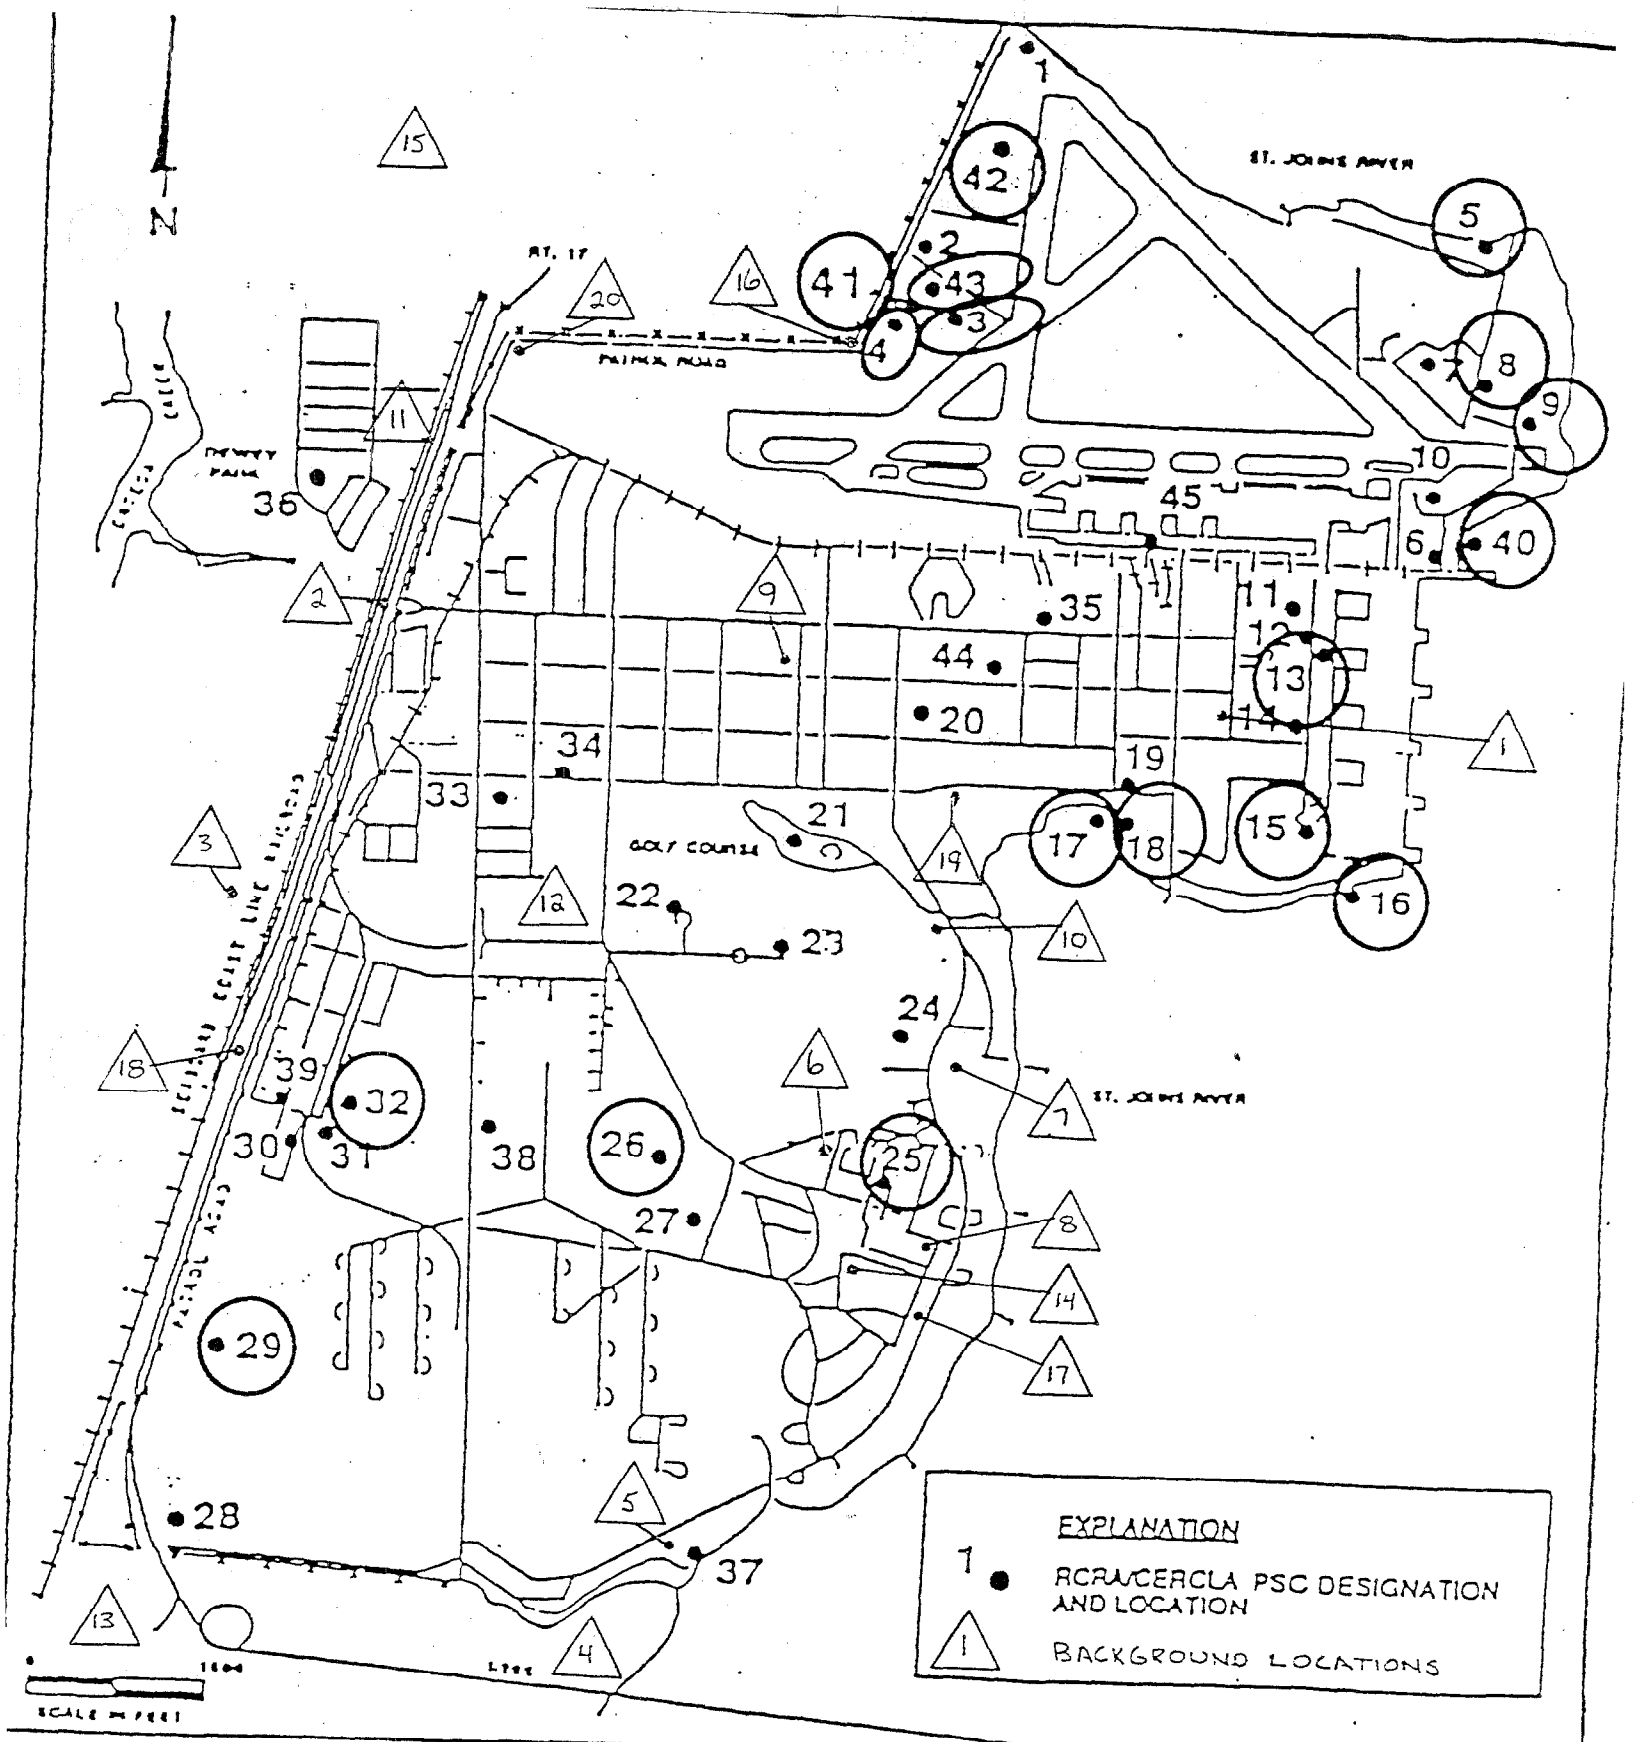
- Aircraft instrument maintenance and repair (radium-226)
- Sandblasting and cleaning (thorium-232)

Standards for both radium-226 and thorium-232 in soil are provided in regulations from the U.S. Environmental Protection Agency (EPA), in 40 CFR 192, "Health and Environmental Protection Standards for Uranium and Thorium Mill Tailings." For concentrations in soil, this value is:

$\leq$ 5.0 pCi/gram above background [1]

Past cleanup and disposal activities involving these materials were based on regulatory standards that have been superseded by standards that are more directly applicable to the radioisotopes of interest and, in many cases, more restrictive than the previously applied standards. The NAS Jacksonville site is being resurveyed to evaluate the existing levels of residual activity for determining the needs of and planning the actions for further remediation.

To support remediation, it is necessary to determine the background activity against which the release criteria will be applied. The background levels for this site have been determined at 20 different locations on the base and around the periphery of the base. The 20 locations are shown on Figure 4-1 and are described in Table 4-1.



PSC Locations

Figure 4-1

RI/FS WORK PLAN FOR OU1

NAS JACKSONVILLE

| 18 | Highway 17 | West side of road, near cement plant |
| 19 | Birmingham | Entrance to NAS-JAX RV park |
| 20 | Perimeter Road | North side of road at first bend after gate |

The background characterization consisted of a series of in situ measurements and soil samples at each location. The in situ measurements consisted of the following:

- Pressurized Ion Chamber (PIC) μR/hr
- Microroentgen Meter μR/hr
- Gamma Flux using 2" by 2" NaI detector cpm
- Beta activity cpm
- Alpha activity cpm

The soil samples were analyzed at an offsite radiochemistry laboratory for the following activities:

- Total Uranium
- Uranium-238 & daughters (naturally occurring)
- Radium-226 & daughters (naturally occurring)
- Thorium-232 & daughters (naturally occurring)
- Potassium-40 (naturally occurring)
- Cesium-137 fallout)

Since radium-226, and thorium-232 were the radioisotopes associated with past site activities, accurate determination of the background contribution was important. During remediation and final gamma clearance surveys, reliance will be placed on the in situ measurements using the μR meter and the 2" by 2" NaI detector. The PIC, used in this background study, will be employed as a secondary measurement standard for background level measurements, in addition to being the primary background dose rate measurement. The performance of the other instruments will be corrected for future application onsite, using the PIC as the secondary standard.

## 4.2 RESULTS - IN SITU MEASUREMENTS

The results of the in situ measurements are summarized in Table 4-2. The complete field logs for each location are provided in Appendix A. The measurements using the PIC were recorded by two different methods. The instrument was operated at each location for 30 minutes with data points plotted on a strip chart approximately 2 seconds apart. At 10 minute intervals, an estimate of the average of a digital readout was recorded in the field log. It was noted from the strip charts that this instrument required 10-15 minutes to stabilize. The value taken from the chart was the average of the final 10 minutes. The sigma ($\sigma$) value recorded for the chart reading is the half-thickness of the plotted data band which denotes the range, rather than statistical variations of the readings. The values obtained from the chart are the background dose rates assigned to each location for all subsequent comparative evaluations.

The 2"x2" NaI gamma values, in Table 4-2, and corresponding beta and alpha readings, summarized in Table 4-3, are a numerical average of three separate readings taken at each location. The sigma ($\sigma$) value shown for each is the variance of the three readings, <u>not</u> the statistics of the counting system. The beta and alpha readings were repeated at each location

with the meter face toward the ground and away from the ground to assess whether a difference exists (e.g., Is the activity directional or uniform?). No statistical difference could be noted between the face-up and face-down readings. The background response is uniform.

During the conduct of the field measurements, two different 2"x2" NaI detectors, two μR meters, and four beta detectors were used. The dashes in the data tables indicate that a particular instrument was not used at that location.

## 4.3 RESULTS - LABORATORY ANALYSIS

Two soil samples were obtained at each background measurement location and were submitted to the General Engineering Laboratory in Charleston, South Carolina, for isotopic analysis. One sample was analyzed for total uranium content using microwave digestion and kinetic phosphorescence analysis (KPA). The second sample was analyzed using gamma spectroscopy to identify the content of uranium-238, radium-226, thorium-232, potassium-40, and cesium-137. These results have been summarized in Table 4-4 with reference to the PIC in situ measured dose rate. The locations have been ordered from lowest to highest measured dose rate. The tables have been organized to present the decay chain activity together for easier comparison. This also facilitates the use of a single dose rate conversion for the entire chain for correlating with the in situ dose rate measurement.

More detailed inspection of the analytical results indicates several anomolies in the data. The uranium-235 values are not consistent with the isotopic ratios anticipated. The uranium-238 and radium-226 values from the gamma spectrum analysis are not consistent with isotopic ratios anticipated. With respect to the uranium-235 values, this data may be disregarded from further consideration. It may be noted that all but five of the analyses resulted in values less than the detection limit. Additionally, evaluation of uranium-235 from the 185 keV photopeak is confounded by the presence of a 186 keV photopeak from radium-226.

The primary issue to resolve for proper definition of the background is the inconsistency between the uranium and radium-226 results. Barring prior geological anomalies that could chemically/physically separate the radium from the uranium decay chain, these elements should be in essential equilibrium. The gamma spectrometry analysis indicates uranium-238 concentrations that are 2-4 times greater than the radium. Conversely, the total uranium from KPA is lower than the radium-226, although generally within a factor of two. Discussion with the lab provided the following observations:

(1) The radium is evaluated using the 609 keV photopeak which will be much more accurate than the uranium 60 keV photopeak, due to much greater compton interference from higher energy photopeaks into the 60 keV photopeak.

(2) The total uranium analysis ((KPA) could be biased low if complete dissolution of the uranium from the sample matrix does not occur. For soil samples, dissolution should be at least 70-80 percent.

Table 4-4 (continued)
Background Summary: NAS Jacksonville
Isotopic Composition - Picocuries per Gram

[1]Locations are arranged in sequence from lowest to highest background reading.
[8]Analysis of 239 keV peak of lead-212, averaged with 3 other peaks.
[9]Analysis of 911 keV peak of actinium-228, averaged with 11 other peaks.
[10]Analysis of 239 keV peak of lead-212, averaged with 2 other peaks.
[11]Analysis of 1,400 keV peak of argon-40.
[12]Analysis of 662 keV peak of barium-137m.

The total uranium KPA results were corrected, assuming a 70 percent recovery from the microwave digestion process. A comparison of the corrected total uranium KPA results for values reported above the detection limit and the corresponding radium-226 results from gamma spectrometry analysis is shown on Table 4-5. The comparison indicates a good correlation which would validate the radium-226 analysis, shown on Table 4-4, as being representative of background concentrations for the uranium-238 decay chain.

## 4.4 CORRELATION BETWEEN IN SITU MEASUREMENT AND LAB ANALYSIS

An analysis was performed to correlate the isotopic composition, determined from the lab analysis, with the in situ dose rate measurement obtained with the PIC. The PIC response is assumed to be comprised of two source components: (1) cosmic radiation, and (2) terrestrial radiation.

Cosmic radiation may be assumed to be a constant at sea level. This value is taken from NCRP-94 as 28 mRem/yr.[2] which equates to 3.19 μR/hr. The remainder of the PIC response will be assumed to be from radioisotopes in the soil.

$$D(PIC) = D_s + D_c$$

$D_s$ = dose rate from soil
$D_c$ = dose rate from cosmic

The soil dose rate is estimated from the laboratory analysis radioisotope concentrations for:

(1) Uranium-238 + daughters
(2) Thorium-232 + daughters
(3) Potassium-40
(4) Cesium-137

Dose rate conversion factors (DCF) were obtained from three reference sources: EPA Federal Guidance Report No. 12[3], RESRAD, a DOE computer model[4], and NUREG-5512, an NRC pathway model[5]. Each set of conversion factors were applied to the lab results for each of two assumptions:

(1) The U-238 gamma photopeak analysis correctly represents the U-238 decay chain.
(2) The Ra-226 gamma photopeak analysis correctly represents the U-238 decay chain.

The total does rate ($D_T$) determined by adding cosmic dose to the soil dose, based on lab concentration results:

$$D_T = D_C + S_V\left(\frac{pCi}{gm}\right)DCF\left(\frac{\mu R}{hr}\Big/\frac{pCi}{gm}\right)$$

Table 4-5
NAS-JAX Background - Uranium vs Radium Analysis

U-238: γ - spec using 60 keV peak (Th-234)

Ra-226: γ - spec using 609 keV peak (Bi-214)

A summary of this evaluation is presented in Table 4-6. This evaluation indicates a very good correlation for the EPA and DOE conversion factors, assuming Ra-226 lab analysis correctly represents the uranium decay chain and a poor correlation assuming the U-238 analysis is correct. The use of the NRC conversion factors results in an opposite conclusion.

Based on the various factors previously discussed, namely better correlation between total "corrected" uranium analysis from KPA and radium-226, and the difficulty in assessing the U-238 60 keV photopeak in the presence of numerous higher energy photopeaks, it is concluded that the gamma spectrometry analysis for radium-226 correctly predicts the concentration of the uranium decay chain in the background. The radium-226 that represents background at the NAS Jacksonville site is given by:

Maximum = 0.99 pCi/gm
Minimum = 0.37 pCi/gm
Average = 0.58 pCi/gm

For conservatism, use the low value, above which the release criteria is added. This implies that remediation has satisfied the criteria for unrestricted release when the residual activity for radium or thorium is:

$S_R \leq 5.4$ pCi/gm

## 5.0 PORTABLE SURVEY INSTRUMENT RESPONSE

To characterize the residual radium-226 activity in situ at NAS Jacksonville, the field instrument readings must be combined with a conversion factor appropriate to the geometry of the residual source. For radium-226, gamma measurement is the most sensitive technique for characterization. Two portable survey meters are utilized for gamma measurement on this site:

- 2"x2" NaI detector - Ludlum 44-10
- μR meter - Ludlum 19

Two in situ source configurations have been considered in the determination of conversion factors:

- distributed (infinite) source
- point source

### 5.1 DISTRIBUTED SOURCE RESPONSE

#### 2"x2" NaI Detectors

The primary instrument to be used for final verification shall be the 2"x2" NaI detector. The μ meter may be used to support the conclusions based on the 2"x2" NaI detector. For performing final verification surveys, assume that the residual activity is comprised of an infinite source of

uniformly distributed activity. The response of the 2"x2" NaI detector to radium-226 uniformly distributed in the soil was determined analytically using the shielding computer code MICROSHIELD.[6] This is shown on Figure 5-1. The normal protocol is to measure on the surface—the upper response curve. Note from this curve that for large excavations (> 5m radius), the response of the detector is approximately:

$$K = \frac{950 cpm}{(pCi / gm)}$$

The criteria for unrestricted release (≤ 5 pCi/gm) would be met for 2"x2" NaI detector response of:

$R_o$ < 4,750 cpm above background

**μR Meter**

The response of the μR meter is based on relationships derived from the background measurements summarized in Table 4-2. A direct comparison was made between the background dose rates, measured with the Reuter-Stokes pressurized ion chamber (PIC), and the μ
meters. These relationships are shown on figures 5-2 and 5-3 for the two μ
meters usedhe relationships that will be assumed applicable to evaluating all subsequent characterization measurements are:

Meter No. 95487 : $R_o$ = [0.76 * (PIC)] - μR/hr

Meter No. 109899 : $R_o$ = [0.53 * (PIC)] - μR/hr

where $R_o$ is the response of the μR meter.

The derivation of the actual dose rate, measured by the μR meter, that will be applied to the characterization data is taken as:

Meter No. 95487 Dγ = [1.32 * $R_o$] - μR/hr

Meter No. 109899 Dγ = [1.89 * $R_o$] - μR/hr

## 5.2 POINT SOURCE RESPONSE

Conversion factors were derived for both the 2"x2" NaI detector and the μR meter for estimating the amount of activity in a radium-226 point source. These relationships were derived from point source attenuation theory and the response of each meter to a cesium-137 point source. These response relationships are shown on Figure 5-4 for the 2"x2" NaI detector and on Figure 5-5 for the μR meter. Note that for both detectors, the measured response deviates from theoretical point source theory at distances approaching contact with the source. This is due to "finite" detector

volume, which approaches a point with increasing distance from the source until the effective source-detector geometry is point-point (theoretical). When using these curves to estimate the activity of a point source from the meter reading, the curves labeled "response" should be used. For the 2"x2" NaI detector on "contact" with an unshielded point source device, the conversion factor to estimate the activity of the source is:

$$K = 35{,}000 \text{ cpm}/\mu\text{Ci}$$

The μR meter is more effective for measuring dose rates from distributed source activity. Characterization readings from the μ
meter will not be used for assess point source activity levels.

## 6.0 DATA ACQUISITION

The radiological characterization of PSC 26 is based upon in situ measurements of gamma, beta, and alpha emissions, and on gamma dose rate measurements. These in situ measurements were supplemented with sample analysis for isotopic identification and quantification. The background in situ measurements (Section 4) were used to derive instrument response functions (Section 5) that were applied to interpretation of PSC 26 characterization data. The background sample analysis was used to identify the composition and range of naturally occurring radioisotopes and to cross-correlate the in situ measurements.

### 6.1 SURVEY INSTRUMENT PERFORMANCE VERIFICATION

At the beginning of each daily characterization effort, each survey instrument was performance checked using a fixed source of radioactivity. This source check was performed using the following NIST traceable sources:

- 2"×2" NaI detector: 1 μCi and 2 μCi cesium-137
- μR Meter: 1 μCi and 2 μCi cesium-137
- Pancake GM detector: 4,016 dpm strontium-90
- Alpha Scintillator: 16,800 dpm thorium-230

The daily response for each detector was plotted on a control chart prepared for each individual instrument. If the instrument response was within the ±20 percent of the initial baseline, the instrument was acceptable for use. If the response fell outside the ±20 percent band, the instrument was removed from service. The results of the daily source checks are provided in Appendix C for all instruments used during the site characterization.

### 6.2 GAMMA WALKOVER SURVEY RESULTS

PSC 26 was surveyed by scanning 100 percent of the accessible surface area. Prior to initiating the scan survey, the grids established by ABB on Figure 2-1 were numbered sequentially, as shown on Figure 6-1. The scan was performed as described in Section 3 using a 2"×2" NaI

Figure 6-1
Grid number Sequence and
Grid Point Identification

detector and ratemeter. Local background was noted for each grid and compared with background values recorded offsite during daily source check to insure the grid survey was not starting over a hot spot. As the grid scan progressed, elevated readings, greater than 20 percent of the startpoint background, were noted. If the scan exceeded twice the startpoint background, the location was noted on a survey map for further detailed characterization. The gamma readings of the southeast corner (coordinates 0,0) of each grid were recorded to provide a profile of local background for the site. The results of these grid intersection measurements are provided in Table 6-1. The field survey logs for the grid point surveys are provided in Appendix D. The field survey logs for the walkover surveys are provided in Appendix E. The background dose rates at five grid point locations around the site, shown on Figure 6-2, were measured using the Reuter-Stokes PIC. These measurements are provided for comparison to the μR meter readings. All grid point μR meter measurements were taken with meter No. 95487. The readings taken at each grid intersection point have been corrected using the value discussed in Section 5.1 These corrected dose rates are provided in Table 6-1.

## 6.3 HOT SPOT CHARACTERIZATION

Upon completion of the walkover scan survey described in Section 6.2, each elevated activity location that exceeded twice the startpoint background was further characterized. This characterization consisted of the following measurements:

- gamma emission rate on the ground surface : 2"X2" NaI detector
- beta emission rate on the ground surface : thin-window pancake GM detector
- alpha emission rate on ground surface : alpha scintillation detector
- gamma dose rate on ground surface : μR meter

A map showing locations of hot spots encountered during this survey is shown on Figure 6-3. A summary of the hot spot activity levels is provided in Table 6-2. The x-y coordinates starting as (0,0) are located in the southeast corner of each grid block.

Several hot spot locations were analyzed in more detail to determine if correlations could be made between the various surface measurements and the level of source activity. Two of those locations, hot spots 20-02 and 40-02, were chosen for sample analysis to confirm the isotopic composition of the contaminants. During excavation for the soil samples, electrical components were encountered at depths reported in the field log as 3-4 in. beneath the surface. Using the point-source/detector response relationship described in Section 5 and shown on Figure 5-4, the activity for each of the hot spot devices was estimated as:

Device 20-02 : $S\gamma = 2.25\ \mu Ci$
Device 40-02 : $S\gamma = 2.90\ \mu Ci$

In situ measurements, taken on the surface and at 1 ft and 3 ft above the surface, were used to determine a gamma flux profile to compare with theoretical profiles, calculated using the computer code MICROSHIELD[6]. The ratio of the 1 ft and 3 ft readings to the contact reading for each of the two in situ hot spots is shown in Figure 6-4 for the theoretical flux profile of a point source as a function of distance beneath the soil surface. The measured ratios at 1 ft and 3 ft

KEUFFEL & ESSER CO.

should be in a vertical line of constant soil thickness. Inspection of Figure 6-4 shows this to be very close to theoretical prediction with projected depths for the two sources of

Device 20-02 : $d_s \cong 6.4$ cm (2.5 in.)
Device 40-02 : $d_s \cong 7.9$ cm (3.1 in.)

This is in very good agreement with the field log that reported the devices approximately 3-4 in. beneath the surface.

Figure 6-5 is the theoretical dose rate relationship at various distances above the surface for a point source of radium-226 at various depths beneath the surface in soil. Using these relationships and the soil depths previously determined an estimate of the initial activity in each hot spot results in

Hot Spot 20-02 : $S\gamma = 2.16\ \mu Ci$
Hot Spot 40-02 : $S\gamma = 7.7\ \mu Ci$

The activity in Hot Spot 20-02 is almost identical to the activity in Device 20-02 (2.16 μCi vs. 2.25 μCi). The activity in Hot Spot 40-02 is approximately two and one-half times as great as Device 40-02 (7.7 μCi vs. 2.9 μCi). This would seem to imply that Device 40-02 has degraded, with significant activity deposited in surrounding soil. This is confirmed by soil sample analysis results in Table 6-3 (Section 6.14) showing minimal soil activity associated with Device 20-02, but almost 2,000 pCi/gm in the sample obtained with Device 40-02. (Note: The difference between the in situ gamma dose rates on Figure 6-5 and the values in Table 6-2 are that the Figure 6-5 values have had the background subtracted.)

Using twice background as the criteria for characterizing hot spots, and assuming source activity of 2-3 μCi, Figure 6-5 would imply that the hot spots characterized would be between the surface and a soil depth of approximately 1 ft (30 cm). For example, a 3 μCi source located 1 ft below the surface would read approximately 6 μR/hr above background at the surface.

In Table 6-2, only the measured gamma dose rate has been corrected using the correlations from Section 5. With the exception of hot spots 63-09, 63-19, and 77-A1, all alpha readings are near or at background. This would imply that the sources of activity are not exposed at the ground surface.

The beta emissions from the radium-226 decay chain have associated beta energies that vary from ~ 1 to > 3 MeV. However, the maximum range of beta particles, even at 3 MeV, is approximately 1.0 cm in soil. The majority of the elevated beta readings may, therefore, be from gamma response to the detector.

The gamma response of the Ludlum 44-0 pancake GM detector, as provided from the vendor, is:

$R\gamma = 3.3$ cpm (μR/hr)

FIGURE 6-5

| | background | 0.82 - 5.22 | 0.82 - 5.22 | 0.82 - 5.22 |

[1] The release criteria is defined as 5 pCi/gm above background. The value stated is the minimum value, determined from offsite measurements, plus the criteria value.

Table 6-4

Sediment Sample Isotopic Composition (pCi/gm)

| Sample ID | Radium-226 | Thorium-232 | Cesium-137 | Potassium-40 |
|---|---|---|---|---|
| 24-01 | 1.14 | 1.59 | 0.194 | 6.29 |
| 25-02 | 0.444 | 0.596 | 0.137 | 2.94 |
| 26-01 (dup) | 0.939 | 0.897 | 0.014 | 4.36 |
| 29-01 | 1.10 | 0.977 | 0.003 | 4.78 |
| 27-02 | 0.668 | 0.970 | 0.0034 | 3.94 |
| 28-02 | 0.766 | 1.03 | 0.038 | 3.30 |
| 30-02 | 1.02 | 1.40 | 0.020 | 6.47 |
| 31-01 | 0.721 | 0.714 | 0.005 | 2.69 |
| 32-02 | 0.642 | 0.887 | 0.052 | 1.80 |
| background | 0.37 - 0.99 | 0.47 - 1.08 | 0.01 - 0.49 | 0.82 - 5.22 |

Each beta reading was compared to the corresponding "corrected" μR meter reading, multiplied by the gamma response factor. Besides the three previously noted hot spots with elevated alpha readings, 16 additional hot spots have elevated beta readings that are approximately a factor of two or greater than the expected gamma response of the detector. This would imply that 19 out of a total of 169 hot spots (or approximately 10 percent) are within 1.0 cm of the surface of the ground.

## 6.4 SOIL SAMPLE RESULTS

A total of three soil samples were obtained on PSC 26. These samples were analyzed for radioisotopic content to confirm the identity of the primary contaminant(s). Two of the samples were taken at hot spot locations that yielded electronic devices as discussed in Section 6.3 The results of the radiochemistry analysis is provided in Table 6-3. The location of these sample points is shown on Figure 6-6. The laboratory analysis reports are provided in Appendix G.

## 6.5 SEDIMENT SAMPLE RESULTS

Eight locations in the moat around PSC 26 and in outfall streams around the PSC were identified for sample analysis. Nine samples were taken from these locations, shown on Figure 6-6. The laboratory analysis reports are provided in Appendix H. The isotopic composition is summarized in Table 6-4. At three of the locations, the radium-226 concentrations were slightly in excess of the range of background discussed in Section 4. However, the highest reading (Location 24-01) of 1.14 pCi/gm is still significantly below the remediation criteria of 5 pCi/gm. At two of the locations, thorium-232 concentrations exceeded the range of background. As with the radium-226 results, however, the highest reading (Location 24-01) of 1.50 pCi/gm is below the remediation criteria for thorium of 5 pCi/gm. Note that both radium and thorium maximums occurred at the same location. For combinations of isotopes, the cleanup criteria will be met if the sum of ratios is less than one:

e.g., $\sum_i \frac{Ci}{Li} \leq 1.0$ where Ci = concentration of isotope $i$

Li = limit for isotope $i$

For location 24-01, this summation, based on a limit for both isotopes of 5pCi/gm, is:

$$\sum_i \frac{Ci}{Li} = .228\ (\mathrm{Ra}) + .318\ (\mathrm{Th}) = .546 < 1.0$$

This result is conservative because the natural background has not been included in the value used for the limit.

# 7.0 SUMMARY OF RESULTS

## 7.1 BACKGROUND SUMMARY

The radiological background for the NAS Jacksonville site was determined by making in situ measurements and taking soil samples for isotopic analysis at 20 locations on and around the site.

The results of this study are used for evaluating the effectiveness of required remedial activities to reduce residual activities below the guidelines established for those activities. Table 7-1 provides a summary of the results of the background study..

## 7.2 PORTABLE SURVEY INSTRUMENT RESPONSE

The background studies were used in conjunction with basic shielding theory, to establish response factors for the gamma measuring instruments employed during PSC 26 characterization. For the instruments used to perform in situ quantification of elevated areas of activity, the response factors are summarized in Table 7-2. Following cleanup activities, the 2"x2" NaI detector will be used to determine if residual activity levels are below the guidelines of ≤ 5 pCi/gm above background. The criteria will be assumed satisfied if the response of the meter is:

$R_0 < 4{,}750$ cpm above background

## 7.3 GAMMA WALKOVER SURVEYS

The walkover surveys were intended to locate areas of elevated activity (hot spots) that had potential to exceed release criteria. Areas that exceeded twice the background of the start point of the grid were marked for further characterization. At each grid intersection, the local gamma background was noted. For the 90 grids in PSC-26, the local background varied from 4.0 μR/hr to 10.6 μR/hr (compared to the NAS-JAX site background that varies from 5.7 μR/hr to 7.8 μR/hr).

## 7.4 HOT SPOT CHARACTERIZATION

As a result of the walkover survey, 169 areas were noted that exceeded twice local background. In situ characterization of these hot spots indicated a maximum surface dose rate of 500 μR/hr. A more comprehensive evaluation of the gamma measurements, analysis of point sources excavated and analyzed ex situ, and instrument response functions indicate that the hot spots evaluated were likely distributed between the surface and a depth in the soil of approximately

1 ft. Inspection of alpha readings at the surface indicates that only three of the hot spots are likely exposed at the surface. Beta particles have a relatively short range in soil. For beta emissions from radium-226 and decay daughters, the maximum range in soil is approximately 1 cm. Each of the elevated beta readings was evaluated as possibly being gamma response of the detector. Using the gamma response function provided by the vendor, 19 hot spots were in excess of values based on comparison to measured dose rate. This would imply that 19 out of 169 hot spots (approximately 10 percent) are within 1 cm of the surface.

## 7.5 SOIL SAMPLE RESULTS

Three soil samples were taken from selected hot spot locations on PSC 26. As expected, the samples contained elevated radium-226 concentrations. Hot spot location 40-02 soil was contaminated to 1,990 pCi/gm. This supports the hypothesis that the device excavated at this location was in an advancing stage of decomposition. The in situ evaluation indicated a source activity of 7.7 μCi compared to an ex situ estimated activity with the device of 2.9 μCi (Section 6.3).

## 7.6 SEDIMENT SAMPLE RESULTS

Eight sediment sample locations were selected in the moat surrounding PSC 26 and in outfall locations downstream from the PSC. Several of the samples exhibited radium-226 and thorium-232 levels in excess of the background range observed around the base; however, these levels are still within the criteria for unrestricted release.

Oak Ridge, Tennessee 37831-0350
Contact: Ms. Lori Keller

Project Description: Cecil Field/JX

cc: BECH00394 Report Date: December 01, 1994 PSC 26 GRID #32 

Sample ID : JX00032 SED
Lab ID : 9411324-09
Matrix : Soil
Date Collected : 11/15/94
Date Received : 11/16/94
Priority : Rush
Collector : Client

SAMPLE FROM MOAT

| Parameter | Qualifier | Result | | DL | RL | Units | DF | Analyst | Date | Time | Batch | M | C |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| **Radiological** | | | | | | | | | | | | | |
| *Gamma PHA - 10 items* | | | | | | | | | | | | | |
| Cesium-137 | J | 0.0522 | +/- 0.0335 | 0.0320 | 0.100 | pCi/g | 1.0 | MDS | 11/27/94 | 1441 | 57406 | 1 | N |
| Potassium-40 | | 1.80 | +/- 0.374 | 0.693 | 1.00 | pCi/g | 1.0 | | | | | | |
| Radium-226 | J | 0.642 | +/- 0.141 | 0.0604 | 1.00 | pCi/g | 1.0 | | | | | | |
| Radium-228 | J | 0.954 | +/- 0.193 | 0.110 | 1.00 | pCi/g | 1.0 | | | | | | |
| Thorium-228 | J | 0.898 | +/- 0.129 | 0.0475 | 5.00 | pCi/g | 1.0 | | | | | | |
| Thorium-230 | J | 0.642 | +/- 0.141 | 0.0604 | 1.00 | pCi/g | 1.0 | | | | | | |
| Thorium-232 | J | 0.887 | +/- 0.128 | 0.0469 | 2.00 | pCi/g | 1.0 | | | | | | |
| Thorium-234 | J | 1.76 | +/- 1.10 | 1.07 | 5.00 | pCi/g | 1.0 | | | | | | |
| Uranium-235 | U | 0.139 | +/- 0.176 | 0.186 | 1.00 | pCi/g | 1.0 | | | | | | |
| Uranium-238 | J | 1.76 | +/- 1.10 | 1.07 | 5.00 | pCi/g | 1.0 | | | | | | |

| M = Method | Method-Description |
|---|---|
| M 1 | HASL 300 |

Notes:
The qualifiers in this report are defined as follows:
J indicates presence of analyte < RL (Report Limit)
U indicates presence of analyte < DL (Detect Limit)
