1.0 INTRODUCTION

1.1 Purpose of Study

The purpose of this study is to provide a sufficiently detailed description of existing environmental conditions in the Flightline Area (Sites LFO4, LFO5, WPO7, and FT09) of Carswell AFB, Texas such that the impacts of documented ground-water contamination beneath the base can be determined and a remedial action can be designed and implemented.

Previous IRP studies documented soil and ground-water contamination, especially with trichloroethene (TCE) and chromium (Cr), in the Flightline Area. Previous investigations detected contamination of soils and ground water only in the "Upper Zone," a term used to describe the surface deposits of alluvium and fill in the Flightline Area (Hargis and Montgomery, Inc., 1983). However, the complete areal and vertical extent of the contaminant plume(s) were not defined.

Previously available evidence suggested multiple sources of the contamination, including source(s) located upgradient of all potential sources in the Flightline Area of the base. The monitoring network existing at that time was insufficient to identify and determine the relative contributions from these other sources. This report, based on additional IRP RI/FS Stage 2 field and analytical efforts performed between 5 March and 22 June 1990, addresses these data gaps and presents a summary of the current understanding of the hydrogeologic setting and Upper Zone ground-water characteristics of the Flightline Area.

Four major field tasks were designed to address existing data gaps. Soil borings were drilled and sampled to better define the distribution of basal gravels deposited in ancient river channels (paleochannels) which might serve as preferential pathways for contaminant migration. Monitor wells were installed to provide additional sampling sites to better characterize the vertical and lateral extent of ground-water contamination and potential or existing contamination sources. A comprehensive sampling of all Upper Zone

wells and numerous surface water sites was conducted to determine the nature and extent of contamination present. Finally, aquifer testing was performed to define the hydraulic conditions in the Flightline Area to aid in a more accurate characterization of contaminant transport.

1.2 Site Description

Carswell AFB is located six miles west of the center of Fort Worth in Tarrant County, Texas (Figure 1-1). The focus of this investigation is on an area near the southern end of the flightline at Carswell AFB, hence the name "Flightline Area" is used to describe the location of the study area.

The Flightline Area includes six discrete sites that were identified as potential sources of contaminants in previous IRP studies (Figure 1-2). They are:

- LF03 - Landfill 3;
- LF04 - Landfill 4;
- LF05 - Landfill 5;
- WPO7 - Waste Burial Area;
- FT08 - Fire Department Training Area 1; and
- FT09 - Fire Department Training Area 2.

Data obtained in the earlier IRP investigations provided no evidence that Sites LF03 and LF08 have released hazardous waste or waste constituents to the environment. Therefore, it was concluded that they do not pose an environmental or human health risk. The monitor wells installed at Site FT08 were, however, included in this most recent Stage 2 ground-water sampling effort because it is likely that they are intercepting ground water that has been contaminated by one or more upgradient, potentially off-base sources. In the following subsections, Sites LF04, LF05, WPO7 and FT09 are described in terms of their physical features, historical uses, and the significant hydrogeologic findings from previous investigations performed in the Flightline Area. Historical descriptions of these sites and the wastes

Figure 1-1. Regional Setting of Carswell AFB, Texas

Figure 1-2. Location of Six Sites Included in the Flightline Area, Carswell AFB, Texas

disposed of in each are taken from the Phase I Records Search (CH2M Hill, 1984).

1.2.1 Site LF04 - Landfill 4

Landfill 4 includes approximately 10 acres of land located east of the south end of Taxiway 197. It was the main landfill during much of the history of Carswell AFB. While in active use, at least six large pits, approximately 12 feet deep, were filled with refuse which was burned and buried. Various potentially hazardous wastes were reported disposed of at this site, including drums of waste liquids, partially full paint cans, and cadmium batteries.

1.2.2 Site LF05 - Landfill 5

Landfill 5 is located northwest of Landfill 4, adjacent to a small tributary to Farmers Branch. The landfill was constructed by building a clay berm along the creek and filling the area behind the berm up to the existing level. The landfill received all types of flightline wastes and refuse. Flightline wastes typically include such substances as oils, thinners, strippers, and paints. Waste materials in the landfill were burned regularly and buried.

1.2.3 Site WPO7 - Waste Burial Area

Site WPO7 is located adjacent to and north of White Settlement Road where it comes to a dead end at the taxiway. The area was used for burial of wastes during the 1960s. Various types of hazardous wastes, including drums of cleaning solvents, leaded sludge, and possibly ordnance were reportedly disposed of at this site.

1.2.4 Site FT09 - Fire Department Training Area 2

Site FT09 is located between Taxiway 197 and the radar facility. This site, with only slight modifications, has been used for fire department

training exercises since 1963. The fire pit is lined with gravel and is enclosed by a low earthen berm. In the past, a second pit was present at the site to collect run-off from the training exercises, but it no longer exists.

1.3 Summary of Previous Flightline Area Investigations

The Flightline Area has been the subject of field investigations performed during two separate Stages of the IRP Phase II; the Stage 1 Preliminary Assessment (PA) and Stage 2 Site Inspection (SI). The Phase II Stage 1 investigation (Radian, 1986) documented contamination of shallow ground water and soils in the Flightline Area. The initial Phase II Stage 2 investigative activities helped define contaminants in the Flightline Area, both qualitatively and quantitatively. Radian conducted a second episode of field activities during the Phase II Stage 2 investigation (Radian, 1990) to fill data gaps remaining after the initial Phase II Stage 2 effort (Radian, 1989). Most notably, further characterization efforts included:

- Source definition;
- Determination of surface water - ground water relationships;
- Definition of vertical and lateral extent of contamination;
and
- Estimation of Upper Zone Aquifer hydraulic properties.

With information obtained from the additional Phase II Stage 2 activities, more complete characterization of contaminant source(s), surface water, geology, and ground water in the Flightline Area was achieved.

The following paragraphs summarize the activities performed throughout the Phase II IRP to characterize the contaminant sources and environmental media of concern in the Flightline Area at Carswell AFB. All field and analytical data from these investigations are contained in the various reports, including the Phase I investigation (CH2M Hill, 1984), the

Phase II Stage 1 investigation (Radian, 1986), and the previous Phase II Stage 2 investigation (Radian, 1989).

1.3.1 Contaminant Source Characterization

The following activities were performed to characterize the source(s) of contamination identified in the Flightline Area:

- Determining the locations of the IRP hazardous waste sites in the Flightline Area;
- Delineating the lateral and vertical extent of the waste areas; and
- Assessing the chemical and physical characteristics of wastes disposed of in the Flightline Area IRP sites.

These activities were accomplished by completing the following tasks:

- Reviewing the Phase I Records Search and personnel interviews;
- Performing geophysical surveys to accurately define the lateral and vertical extent of the former waste disposal areas; and
- Collecting environmental samples (soil, ground water, and surface water) to determine the types and amounts of contaminants associated with individual waste disposal units within the Flightline Area.

1.3.2 Surface Water Characterization

The major surface water features associated with the Flightline Area are:

- Farmers Branch;
- An unnamed tributary that flows into Farmers Branch; and
- Two ponds located on the Carswell AFB golf course.

The following tasks were performed to characterize these surface water features:

- Chemical analysis of surface water samples collected from Farmers Branch, the unnamed tributary to Farmers Branch, and the two ponds located on the golf course;
- Estimating flow volumes at several locations on Farmers Branch and the small tributary; and
- Installing and surveying a staff gage in Farmers Branch to help determine ground-water/surface water relationships in the Flightline Area.

1.3.3 Geologic Characterization

The objectives of the geologic characterization activities performed in the Flightline Area were to:

- Determine the location of paleochannel(s) to assist in placement of Upper Zone monitor wells;
- Determine the depth to the shallow aquitard (Goodland/Walnut Formation) in the Flightline Area;
- Identify the thickness of the shallow aquitard under the Flightline Area; and
- Determine the depth to the uppermost regional potable water supply aquifer (Paluxy Aquifer) beneath the study area.

Radian accomplished these activities by completing the following tasks:

- Borehole drilling, sampling, and lithologic logging; and
- Performance of geophysical surveys.

1.3.4 Ground-Water Characterization

Investigations of the ground water occurring under the Flightline Area were limited to the Upper Zone and the Paluxy Aquifers. Previous investigations focused on these two aquifers because deeper aquifers are unlikely to be affected by downward migrating contaminants. This is due to the several hundred-foot thick section of low permeability Glen Rose Limestone that acts as a basal aquitard to the Paluxy Aquifer in this area. Activities were focused on defining ground-water quality, both upgradient and down-gradient of former waste disposal units in the Flightline Area, and on estimating aquifer properties. Characterization efforts were directed toward:

- Determining the physical and hydraulic properties of the aquifers;
- Identifying and quantifying the concentrations of contaminants in ground water from the Upper Zone and Paluxy Aquifer; and
- Delineating the lateral and vertical extent of ground-water contamination.

Radian performed the following tasks to characterize ground-water conditions in the Flightline Area:

- Test well installation in both the Upper Zone and Paluxy Aquifers;
- Sampling and describing the sediments that contain the ground water;

- Synoptic water-level surveys and potentiometric surface contouring;
- Performing in situ permeability tests (slug tests) and a pump test of the Upper Zone Aquifer;
- Ground-water sampling and analysis for waste-specific indicator parameters; and
- Mapping of ground-water contamination in the Flightline Area.

1.3.5 Findings of Previous Flightline Area Investigations

Geology

Based on the results of previous investigations (CH2M Hill, 1984; Radian, 1988), the Flightline Area of Carswell AFB is characterized by surficial alluvial deposits of gravel, sand, silt and clay which are unconformably underlain by limestone and shale bedrock of the Cretaceous Goodland and Walnut Formations. The alluvium includes flood-plain and fluvial terrace deposits which together constitute the Upper Zone, as defined by Hargis and Montgomery, Inc., 1983.

The base of the Upper Zone sediments was encountered during drilling activities performed in both RI/FS Phase II Stage 1 and Stage 2. In the Flightline Area, the Upper Zone varies from approximately 13 feet to greater than 40 feet thick. In general, silt and clay, with variable amounts of sand and gravel, dominate the upper five to WPO7 feet of the section. Below this depth, sand and gravel occur in increasing proportions, and in general, tend to increase in grain size with depth. Basal gravel deposits also occur in paleochannel features eroded into the surface of the underlying bedrock. The gravel consists mainly of limestone and shell fragments that range in size from fine gravel to cobbles.

The bedrock was penetrated during drilling of the Paluxy Aquifer monitor wells in the Stage 2 study, and was encountered at the base of a number of the Upper Zone monitor wells installed in Stage 1 and Stage 2. Bedrock in the Flightline Area consists of interbedded fossiliferous limestone and calcareous shale of the Goodland and the Walnut Formations. These units are generally dry, although small amounts of water were occasionally observed in the shale and clay units during drilling activities.

The bedrock surface is level across most of the Flightline Area east of Taxiway 197, but rises sharply near the southwest part of Site FT09 and the southern part of Site LFO4, in the vicinity of the outcrop south of the study area. The locally irregular topography of the bedrock surface is typical of an erosional surface modified by fluvial processes.

Ground Water

Ground water occurs in the Upper Zone and in the Paluxy Aquifer beneath the Flightline Area. The potentiometric surface of ground water in the Upper Zone tends to mirror the configuration of the alluvium/bedrock contact. The position of the water table also reflects to a lesser degree the land surface topography. Downgradient is generally to the east toward a tributary of Farmers Branch, parallel to the surface slope. The hydraulic gradient is very low (on the order of 16 feet per mile) beneath most of the Flightline Area, except in the extreme southwestern area where it is notably steeper.

IRP Stage 1 ground-water analytical results revealed Upper Zone contamination by several volatile organic compounds, most notably TCE at concentrations ranging up to approximately 5000 micrograms per liter ($\mu\text{g}/\text{L}$). Soil samples from the Flightline Area also contained detectable concentrations of TCE. Most of the detected contamination was apparently centered to the east of the Flightline Area at the golf course, but TCE concentrations up to nearly 3300 $\mu\text{g}/\text{L}$ were also detected in samples from wells located upgradient of Landfill 5, within 900 feet of the flightline. No contaminants were detected in the Paluxy Aquifer monitor wells.

During the Stage 2 effort, flightline monitor wells were sampled in January-February, and again in April, 1988. The following analytes were detected in concentrations above their respective EPA Maximum Contaminant Levels (MCLs) in one or more samples: arsenic, barium, cadmium, chromium, lead, selenium; and trichloroethylene, vinyl chloride, and benzene. Of the metals detected in concentrations exceeding their MCLs, chromium was the most widespread. However, all metals analyses were performed on unfiltered ground-water samples, and therefore reflect total, rather than dissolved metals concentrations.

As determined in Stage 1, the dominant organic contaminant identified in Stage 2 Upper Zone ground-water samples was TCE. The extent of the TCE plume in the Flightline Area was not completely defined upgradient (west) or downgradient (north and east) of the flightline IRP sites. Based on the generally west-to-east shallow ground-water flow direction, the existence of TCE in samples from monitor wells located west of the IRP sites was interpreted as indicating one or more additional upgradient sources not related to the sites subject to ongoing investigation. Also, TCE contamination of Upper Zone ground water in the area east of Air Force Plant 4 (i.e., upgradient of the Carswell AFB Flightline Area) is documented (Hargis and Associates, 1989).

Additional Stage 2 activities in the Flightline Area were recommended to: 1) determine to what extent, if any, the TCE-contaminated Upper Zone ground water east of Plant 4 and that beneath the Flightline Area constitute a contiguous plume; 2) determine to what extent, if any, the IRP sites on Carswell AFB are contributing to the existing Upper Zone ground-water contamination; 3) define the maximum lateral, downgradient, and vertical extent of the contaminant plume on Carswell AFB; and 4) define the site-specific hydrogeological characteristics of the Upper Zone in the Flightline Area in sufficient detail to design and implement an appropriate remedial action.

1.4 Report Organization

Following this Introduction, the field activities performed to characterize the Flightline Area are described in Section 2. The techniques and methodologies used to accomplish the field program are presented in detail with respect to the contaminant source, surface water, geological, and ground-water investigations that were included in the comprehensive Phase II scope of work. Section 3 presents a detailed description of the physical environmental setting of the Flightline Area based on interpretation of data from the current investigation and from previous studies. The nature and extent of surface water and ground-water contamination, determined from the most recent round of sampling and analysis (May-June 1990) are discussed in Section 4, and Section 5 addresses contaminant fate and transport.

2.0 FIELD TECHNIQUES AND ANALYTICAL METHODS

Several field techniques were used to obtain information on the environmental conditions of the Flightline Area. The following subsections describe the techniques for drilling and soil sampling (including analytical methods, holding times, and collection and preservation requirements), the methods for conducting geophysical surveys, the methods and specifications for well construction and development, the techniques for collecting water samples (including analytical methods, holding times, and collection and preservation requirements), aquifer test methods, and surveying requirements.

2.1 Drilling and Soil Sampling

Drilling at Carswell AFB was accomplished using a hollow-stem auger rig for the Upper Zone monitor wells and soil borings and a rotary drilling rig (using both mud and air) for the Paluxy monitor wells. These methods were selected based on site-specific conditions and data requirements; i.e., the anticipated depth of completion, the need for water-level observations during drilling, and the expected geologic conditions.

After each borehole was completed, the drilling rig, auger flights, and equipment were decontaminated with a high temperature, high pressure steam-sprayer using base potable water.

Cuttings suspected of being contaminated on the basis of visual evidence and organic vapor analyzer (OVA) or photoionization detector (HNU) readings were placed in steel 55-gallon drums. Selected samples of cuttings were collected and submitted for analysis of EP Toxicity.

The following paragraphs describe the drilling and soil sampling procedures.

2.1.1 Hollow-Stem Augering

A Mobile Drill B-61 or a CME-75 hollow-stem auger drilling rig was used to perform shallow soil borings and installation of the Upper Zone monitor wells. The hollow-stem auger method allows for recovery of relatively undisturbed subsurface soil cores, determination of subsurface lithologies and structures, and accurate identification of the position of the water table. The boreholes were drilled dry; no drilling fluids or additives were used. Samples of soil were collected with either a split-spoon sampler, a thin-wall sampler (Shelby tube), or a CME 5-foot continuous core sampler.

The soil samples were described in terms of lithology, moisture content and any evidence of contamination. Lithologic logs of boreholes drilled during the most recent field activities are provided in Appendix A. Photographs of selected soil cores showing lithologic characteristics were also taken.

Selected samples were shipped on ice to Radian's laboratory for chemical analysis. Analytical parameters for soil samples are listed in Table 2-1. No soil samples were collected for chemical analysis in the most recent Stage 2 effort.

2.1.2 Air and Mud Rotary Drilling

Air and mud rotary drilling was performed during the Phase II Stage 1 program (1985) with a Gardner-Denver 1500 CD truck-mounted rig. A 6-inch bit was used to advance a pilot borehole through the Upper Zone alluvial material to a depth of at least five feet into the underlying Goodland Limestone. The borehole was then reamed to a diameter of 14 inches. In order to seal off different water bearing zones, a 10-inch diameter steel casing was installed to the full depth of the borehole and the annular space was grouted. Upon achieving a positive seal, the borehole was advanced using a 6-inch diameter bit to the final depth at the shale unit separating the upper and lower Paluxy Formation. Bentonite drilling fluid was used while drilling in

the Paluxy Formation owing to borehole instability during air rotary operations.

As the borehole was advanced, the cuttings discharged at the surface were described by lithology, moisture content (air rotary-drilled section), evidence of contamination, and other features useful in characterizing the geologic section. Drilling conditions, such as relative rate and ease of penetration, were noted by the driller. Water encountered during drilling was noted with respect to depth of occurrence and rate of production. As needed, drilling was suspended temporarily to allow for recovery of water in the borehole.

2.2 Geophysical Surveys

Geophysical surveys were performed to define the vertical and lateral extent of waste-disposal activities, to provide a clearer picture of the subsurface conditions around the sites, and to investigate the potential existence of buried objects at several locations. Most geophysical tasks were performed during Phase II Stage 1; only a magnetometer survey of WPO7 (formerly Site 10) was performed during the initial Stage 2 investigation.

All survey grids were laid out using a compass and measuring chain. Stations were marked with labelled pin flags or spray paint. The geophysical techniques employed in the Flightline Area characterization efforts were earth resistivity, magnetic and magnetic gradient, and fixed frequency electromagnetic profiling (EMP) conductivity. The Earth Technology Corporation of Golden, Colorado performed the geophysical surveys in the Flightline Area. Following are brief descriptions of the various geophysical techniques used to characterize the Flightline Area.

2.2.1 Electrical Resistivity

Earth resistivity was measured by direct current Schlumberger soundings (vertical electrical soundings - VES) at all IRP sites in the Flightline Area. The Bison Model 2350 Earth Resistivity meter was utilized

for the VES measurements. Current electrode separations used were (in meters): 1, 2, 3, 4, 6, 10, 14, 20, 30, 40, and 50 (1 meter equals 3.28 feet). Due to variable ground conductivity, potential electrode separations varied slightly from site to site. The sounding data were processed using the ABEM VES iteration process to obtain a best fit curve and were plotted logarithmically as resistivity in ohm-meters versus half the current electrode separation in meters. The plot also includes the layered earth model giving the best match. At most VES sites, orthogonal electrode arrays were used to test for distortions of the data due to lateral inhomogeneities in the ground.

2.2.2 Electromagnetic Surveys

Electromagnetic profiling (EMP) surveys were conducted at Flight-line Area Sites LFO3, LFO4, LFO5, WPO7, FTO8, and FTO9 using two devices: the Geonics EM31 and the Geonics EM34-3 ground conductivity sensors. Both ground conductivity sensors are designed for rapidly obtaining data over large areas. The meters employ magnetic dipoles or magnetic induction loops for transmission and reception of low frequency electromagnetic waves. The effective depth of investigation of the EM31 is six meters; the depth of investigation provided by the EM34-3 depends on the coil separation and orientation, applied frequency, and to some extent, the conductivity profile of the subsurface. The techniques and conditions at Carswell AFB resulted in an effective investigation depth of 50 feet with the EM34-3. The resulting data are reported in units of millimhos/meter.

2.2.3 Magnetometer Surveys

Magnetometer surveys were accomplished using either an EDA PPM500 proton magnetometer or a Geometrics G856AX magnetometer. Magnetometer surveys were performed because the over-burden at Carswell has a low magnetic susceptibility; the buried objects were believed to contain a significant amount of iron that would create a noticeable magnetic anomaly. Readings of the total field and magnetic gradient were taken at each location. The units for these readings are gammas and gammas per one-half meter (1.64 feet), respectively. The magnetometer survey of WPO7 during Phase II Stage 2 activities was

performed to determine if metal objects were buried at any of the proposed drilling locations.

2.3 Monitor Well Construction and Development

During the Phase II activities in the Flightline Area, a total of 35 Upper Zone monitor wells and two Paluxy Aquifer monitor wells were installed. The construction specifications and well development procedures are described in the following sections. One aquifer (pump) test well and an observation well were also completed in the Upper Zone. The construction of these wells is described in Section 2.5 (Aquifer Pumping Test).

2.3.1 Upper Zone Well Construction

Upper Zone monitor wells were installed either immediately after completion of the drilling operations or after the borehole produced enough water to warrant a well. Construction specifications for the Upper Zone monitor wells are presented in Table 2-2. Well completion summaries for Flightline Area monitor wells completed in the most recent (1990) investigation are provided in Appendix B. Construction methods were generally consistent with the specifications provided in the SOW. Any changes necessitated by unanticipated field conditions were made with the knowledge and approval of the HSD/YAQ Technical Program Manager. Decisions regarding the setting of the screen and casing, length of screen, amount of sand pack and bentonite were made in the field by the Radian Supervising Geologist based on the static water level and saturated thickness of Upper Zone sediments. Monitor wells were installed using the following procedures:

1. Prior to installation, the casing and screen sections were thoroughly washed using a high temperature, high-pressure steam sprayer, with base potable water.

TABLE 2-2. UPPER ZONE MONITOR WELL CONSTRUCTION SPECIFICATIONS,
FLIGHTLINE AREA, CARSWELL AFB, TEXAS

-
1. Casing: Two-inch diameter, threaded and flush jointed, Schedule 40 PVC.
 2. Screen: Two-inch diameter, threaded and flush-jointed factory-slotted, Schedule 40 PVC, 0.020 inch slot. Normal screen length is 10 feet. Some well screens were wrapped with filter fabric material.
 3. Sand/gravel pack: Washed and bagged, rounded sand/gravel with grain size compatible with screen slot and formation (Coarse, No. 8-20). A sand pack was placed from the bottom of the borehole to two to five feet above the top of the well screen. Sand was placed at a controlled rate to avoid bridging within the auger.
 4. Bentonite seal: Two feet (minimum) of pelletized bentonite placed above the sand pack.
 5. Grout: Type II Portland cement grout poured into the annular space from the top of the bentonite seal to land surface. A grout mixture consisting of approximately four pounds of bentonite to 94 pounds of cement was used. The grout was allowed to set for at least 24 hours before any well development activities.
 6. Surface completion: PVC casing cut off to provide a 2- to 3-foot stickup with a solid cap placed on the casing. A 4- to 6-inch square steel well protector, four to five feet in length, was placed over the exposed PVC casing, and seated in the cement. A locking cap is incorporated in the well cover. Steel guard posts were installed as described in (8) below. The steel well protector and steel guard posts were painted for corrosion control and visibility.
 7. Alternate flush completion: PVC casing cut off two to three inches below land surface, with a cast-iron valve box cemented in place. To prevent any surface water infiltration, the valve box is slightly elevated above land surface and the surrounding concrete is sloped away from the well. The lid to the valve box is secured with allen bolts. Most wells located on the heavy traffic areas of the Carswell AFB golf course were completed flush with the land surface.
 8. Guard pipes or posts: Three 3-inch diameter steel posts, six feet in length, with a minimum of two feet below ground, installed radially four feet from the wellhead (not emplaced for flush surface completion).
-

2. Screen and casing sections were assembled, then lowered carefully into the borehole. As the string of screen and casing was lowered, additional sections of casing were added until the bottom of the screen reached the bottom of the borehole. The top of the casing was capped to prevent any completion materials (sand, bentonite pellets, and grout) from entering the casing during well construction activities. Where heaving or flowing sand was encountered, some well screens were wrapped in a filter fabric and installed using a natural, rather than artificial, sand pack. These wells were LF04-4F and -4H, and LF05-5F, -5G, and -5H.
3. Except as previously noted, clean sand (Coarse, No. 8-20) was poured carefully inside the annular space as the augers were slowly withdrawn from the borehole. The sand pack was regularly measured by the supervising geologist until the level of the sand was at least 2 feet above the top of the screen. Bentonite pellets were placed above the sand to form a 2-foot thick seal (minimum). If necessary, water bailed from the borehole was poured down the annular space to hydrate the bentonite.
4. Neat cement grout containing approximately four percent bentonite was either emplaced through the augers as they were withdrawn, or slowly poured down the borehole, if the formation was sufficiently consolidated to remain open.
5. After completion of grouting, the casing was cut two to three feet above land surface and a protective 4- to 6-inch diameter steel casing protector with a lockable lid was cemented into place. Three steel guard posts were then placed around the well. If above-ground stickups were of concern in an area, the well was completed flush with the land surface. For flush completions, the lid to the valve box was secured with allen bolts.

After all wells were completed, well locations and elevations were professionally surveyed. Table 2-3 presents the elevations of the ground surface, the wellhead, and the screened interval of the Upper Zone monitor wells in the Flightline Area.

2.3.2 Paluxy Formation Well Construction

After drilling operations were completed as described in Section 2.1, two Paluxy Aquifer monitor wells were installed as follows: Screen and casing, consisting of 5-inch diameter Schedule 80 PVC, were installed into the 10-inch diameter borehole. Screen length was 37.5 feet. Gravel pack material (Texas Blast Sand No. 1A) was placed in the annular space to a level of five feet above the top of the screen. Bentonite pellets were added to form a 2-foot thick seal, and the remaining annular space was sealed to the surface by the tremie method using bentonite-cement grout. After the grout was allowed to set for a minimum of 24 hours, the well was developed by bailing until a sediment-free discharge was produced. A 1/3 horsepower stainless steel submersible pump was installed after development. Protective casing, surface electrical connections, and a concrete well pad were placed after the pump was installed.

2.3.3 Well Development

After allowing the cement grout to set-up for a minimum of 24 hours, the Upper Zone wells were developed by either bailing using a bottom-entry bailer or pumping with a Triloc® hand pump (1.7-inch diameter). As previously stated, Paluxy Aquifer monitor wells were developed by bailing.

Water levels in some of the Upper Zone wells recovered slowly and the wells were bailed dry several times. Other wells produced sufficient water and were developed in a single effort, without a recovery period. Development was considered complete when the water in the well was relatively sediment free, or pH, temperature and conductivity had stabilized. The ground water removed from the wells was placed in steel 55-gallon drums, sealed and

appropriately labeled, based on field observations. Well development logs for the most recently installed (1990) monitor wells in the Flightline Area are provided in Appendix C.

2.4 Water Sampling

Both ground-water and surface water samples were collected from the Flightline Area. The following subsections describe the sampling techniques and methodologies for the various water samples collected during IRP Phase II investigations. Ground-Water and Surface Water Quality Sampling Records for the most recent round of Stage 2 sampling, including measurements of pH, conductivity, and temperature; and information such as volumes of water purged prior to sampling are provided in Appendix D.

2.4.1 Surface Water Sampling

Surface water grab samples were collected directly in the clean sample containers to minimize sample handling (and possible cross-contamination). The samples were collected approximately six inches below the water surface, or half-way between the water surface and the bed of the stream if the stream was not six inches deep. During the most recent (1990) field activities, surface water samples were collected at Farmers Branch, a small tributary that runs into Farmers Branch, and two ponds located on the Carswell AFB golf course. Additionally, during the most recent Stage 2 investigation (1990), estimates of flow volume were made at each surface water sample location at the time of collection.

Specific conductance, pH and temperature were measured on an aliquot of each sample. Specific conductance and pH were measured with a DSPH-1 meter and the temperature was taken with a mercury thermometer. Alkalinity measurements were made in the field using a Hach Alkalinity Test Kit (Model AL-DT) and digital titrator. Prior to obtaining the field measurements, the pH meter was calibrated with pH 4, 7, and 10 standard solutions and the conductivity meter was calibrated using either a 1413 or a 1504 umhos/cm %Cl conductivity standard solution.

2.4.2 Ground-Water Sampling

Prior to sample collection, water levels were measured in each of the monitor wells with an Olympic Actat water level meter, and were recorded in a field notebook or on appropriate IRPIMS data collection forms. Measurements were taken from the surveyed mark point at the top of the casing, and read to the nearest 0.01-foot. Between measurements, the probe and associated electrical line were washed with laboratory grade detergent, rinsed with potable water, and then rinsed with deionized water to reduce the possibility of cross-contamination.

Before samples were collected, a minimum of three well volumes of water were bailed from the well using a bottom-entry Teflon™ bailer attached to a nylon monofilament line. This procedure ensured that representative formation water was collected. Purged water was placed in 55-gallon drums for final disposal pending the outcome of chemical analyses (provided to the Base Environmental Coordinator). Between wells, all equipment used for bailing operations was cleaned with laboratory grade detergent (Alconox), rinsed with potable water, ASTM Type II Reagent Water (or approved equivalent), pesticide-grade methanol, and finally pesticide-grade hexane. The equipment was allowed to air dry completely before reuse. The nylon line was replaced between wells.

Specific conductance, pH, temperature, and alkalinity were determined as described for surface water. On a few occasions, field measurements could not be made due to instrument malfunction.

After each well was purged of the required volume of water, ground-water samples were collected using a Teflon bailer. After collection, samples were placed directly into pre-labeled sample bottles and preserved according to the requirements listed in Table 2-4. Ground-water samples for dissolved metals were filtered in the field. Samples were placed in ice chests with ice and were shipped for overnight delivery to Radian's laboratories in Sacramento, California, or Austin, Texas; or were hand delivered to the laboratory in

Austin. To ensure that sample integrity was maintained during shipping and handling, custody seals were affixed to each ice chest and chain-of-custody forms were completed and transmitted with the samples to each laboratory.

2.5 Aquifer Testing

Single-well in situ permeability aquifer tests (i.e., slug tests) and an aquifer pumping test were performed to determine the hydraulic properties of the Upper Zone Aquifer in the Flightline Area. Following is a discussion of the aquifer test methods.

2.5.1 Slug Tests

Slug tests were performed in 13 monitor wells (LF04-4A, -4B, -4D, -4E, -4G, LF05-5A, -5B, -5C, -5D, -5E, FT09-12A, -12B, and -12C) at the Flightline Area, and results were used to calculate the hydraulic conductivity of the Upper Zone Aquifer. The wells selected for slug testing represent a range of hydrogeologic conditions.

The slug test evaluates the response of water levels in a well when a "slug" (known volume) of water is instantaneously removed or added. Typically, the response of the water level in a moderately permeable formation, such as the Upper Zone at Carswell AFB, is quite rapid. By determining the behavior of the water level in the well in response to the stress of the slug, the hydraulic conductivity of the aquifer material directly adjacent to the well screen can be calculated. To perform these calculations, the geometry of the well, aquifer boundary conditions, and initial water level must be known. The hydraulic conductivities were calculated using the method developed by Bouwer and Rice (1976).

The first step of the slug test was to measure the static water level in the well. Next, a known volume of water was removed by bailing and segregated for use as the slug. After the desired volume of water was removed from the well, a pressure transducer and attached cable were lowered into the well and suspended at a point just above the bottom of the well screen. The

pressure transducer was connected to an In-Situ, Inc. Hermit 1000B automatic data logger, capable of measuring and recording pressure changes on a logarithmic frequency, beginning every 0.2 seconds in the first few seconds of the test. Before introducing the slug, the water level in the well was allowed to return to static conditions. Then, as the slug was rapidly poured in the well, the data recorder was activated to measure the response of the water level. At least two slug tests were conducted at each well tested to determine the reproducibility of the results.

2.5.2 Aquifer Pumping Test

An aquifer pumping test was performed to evaluate the hydraulic characteristics of the Upper Zone deposits in the Flightline Area. One 6-inch diameter well (LF04-03) was installed during field activities performed under D.O. 4 Modification 0004 to accommodate the 4-inch submersible pump used in the test. The pumping well was constructed of Schedule 80 PVC (slot size 0.020 inches) and was screened over the entire saturated thickness of the Upper Zone. A 2-inch diameter observation well (LF04-02) was also installed. The location of this observation well is about 50 feet north of the pumping well. The observation well was also screened over the entire saturated thickness of the Upper Zone. All other construction details were the same as for the Upper Zone monitor wells.

Pumping tests usually provide the means to stress an aquifer to such a degree that reliable estimates of transmissivity, storativity, and hydraulic conductivity can be made. These values are calculated using drawdown and recovery data recorded in the pumping well and observation wells. Each of these calculated parameters can ultimately be used to estimate groundwater flow rates and contaminant plume migration.

Step Pumping Test

Prior to the start of the pumping test, a step test was performed to establish the optimum pumping rate. A step test is used to assess aquifer response at multiple incremental pumping rates to determine the optimum

pumping rate for the aquifer test. The optimum pumping rate for the Flight-line Area pumping test was determined to be the full capacity of the submersible pump (Gould 1/2 HP, Model 10 EJ) or approximately 20 gallons-per-minute (gpm). The pump was rated at approximately 25 gpm with the amount of hydraulic head encountered in the pumping well. However, travel of discharge water through over 300 feet of polyethylene pipe before ultimate discharge to the City of Fort Worth sewer system reduced discharge rates because of friction losses. Background water-level data in the pumping well and the near observation well were collected electronically (at 10 minute intervals) with a Hermit brand model SE1000B data logger for approximately 40 hours prior to the step test. The background data are useful for defining natural trends (i.e., variability) in the Upper Zone Aquifer water level, such as increases from recharge or decreases due to evapotranspiration. The background data can also be useful in preventing misinterpretation of a water level decline as being caused by pumping, rather than by natural factors.

Pumping Test

The pumping test was conducted on 21 and 22 June 1990, and ran for 20 hours. The pumping test began about 16 hours after the end of the step test, when the measured water levels had recovered to over 99 percent of their pre-step test levels. The 4-inch submersible pump (used in the pump and step test) was powered by a 3500 watt portable generator. Pump test discharge water underwent aeration before being discharged to the City of Fort Worth sewer system, with air for the aeration provided by a portable 125 cfm air compressor. During the step and pump tests, the pumping rate was determined by timing discharge into a 5-gallon container with a stopwatch. All required data from the aquifer test were recorded on IRPIMS Pump/Recovery Test Data Collection Forms, included in Appendix F.

Because drawdown is more rapid at the beginning of a pumping test, electronic recording of water levels (in the pumping well and nearest observation well) was in a logarithmic progression. Manual water level measurements of seven additional Upper Zone monitor wells were also made at more frequent intervals during the early stages of the test. During the test, pH,

conductivity, temperature and the visual characteristics of the discharge water were recorded at regular intervals. In addition, the pumping rate and drawdown of the pumping well were periodically checked to ensure consistency throughout the test, as wells will typically show a slow decline in discharge with time as drawdown increases.

Electronic data logging equipment was periodically downloaded by hand during the test. This allowed for construction of time-drawdown plots, or hydrographs, in the field for all wells being monitored during the test. These plots were used for preliminary determination of aquifer characteristics. Discharge water was pumped into a temporary holding tank to allow observation of water characteristics and recording of water quality data. Periodically during the pump test, water samples going into the holding tank (pre-aeration) and exiting the holding tank (post aeration) were collected. These samples were collected in 40 mL VOA vials, filling each approximately two-thirds full with water. These water samples were allowed to sit in the direct sunlight for several hours prior to a headspace analysis for volatile organic content. During the time spent in the sunlight, volatile organics in the ground-water volatilized to the overlying air column. The volatile organic content of the air (headspace) was measured with an HNu photo-ionization detector (PID). This was accomplished by cutting a small slit in the Teflon™ septum in the cap of the vial and quickly inserting the probe of the HNu PID. Comparison of the pre-aeration and post-aeration volatile organic concentrations allowed for gross determination of the aeration system efficiency.

At the conclusion of the 20-hour ground-water pumping period, water level monitoring and observations continued during the recovery period. Recovery data were included on the hydrographs for each well. Data from the aquifer pumping test were used to calculate hydraulic parameters for the Upper Zone Aquifer.

A more complete description of the aquifer pumping test procedures and methods of analysis is provided in Appendix F.

2.6 Surveying

Land surveying activities were conducted by Brittain & Crawford, Inc., Registered Land Surveyors, of Fort Worth. These activities consisted of measurements of the horizontal location of wells, boreholes, hand-auger holes, and surface water sampling locations in terms of State Plane Coordinates; and of measurements of reference point elevations to an accuracy of ± 0.01 foot. The survey was conducted to an accuracy needed for a second order survey. All of the data were provided as values posted on a map, and in tabular form (Appendix E).

3.0 PHYSICAL CHARACTERISTICS OF THE FLIGHTLINE AREA

This section describes the physical characteristics of the Flightline Area, with respect to local surface features, surface water bodies, geology, and ground-water occurrence. The primary basis of this characterization is interpretation of field and laboratory data obtained from the Installation Restoration Program (IRP) at Carswell AFB, Texas. Radian maintains a database containing all environmental data from the Flightline Area developed during the Phase II Stage 2 field program using the U.S. Air Force required Installation Restoration Program Information Management System (IRPIMS) format.

3.1 Topographic Surface Features

The area in the vicinity of the flightline ranges from an essentially level surface near the main (north-south) runway to gently rolling land near tributaries of Farmers Branch at the golf course. Figure 3-1 shows the location of the various surface features associated with the Flightline Area (buildings, roads, IRP sites, surface water bodies, etc.).

The Soils Conservation Service has identified four soil associations at Carswell AFB, however, only the Sanger-Purves-Slidell association occurs in the Flightline Area (USDA, 1981). The Sanger-Purves-Slidell soils range in thickness from 8-80 inches and are predominantly composed of clay loam. These are nearly level to gently sloping clayey soils with a permeability ranging from $<4.2 \times 10^{-5}$ to 3×10^{-4} cm/sec.

All of the land is underlain by terrace deposits of the Trinity River and fill material associated with the construction of the base runway and taxiways. The terrace deposits have been moderately dissected by tributaries of Farmers Branch. Elevations in the area range from approximately 625 feet mean sea level (MSL) at Landfill 3 (LFO3) to 580 feet MSL at the northern end of Landfill 5 (LFO5) and at Site 11 (FTO8).

Figure 3-1. Prominent Surface Features in Flightline Area, Carswell AFB, Texas

3.2 Surface Water

The main surface water bodies in the Flightline Area are Farmers Branch, an unnamed tributary that flows into Farmers Branch, and two ponds on the Carswell AFB golf course. Surface drainage in the Flightline Area is generally to the north and east toward Farmers Branch. During the Stage 2 investigation performed in 1990, water was present in tributaries to Farmers Branch at 1) the southwest side of Landfill 4 (LF04), 2) the eastern side of Landfill 5 (LF05) and Site 12 (FT09), and 3) the eastern edge of the Flightline Area (see sample location LF05-07, Figure 3-1). Southwest of Landfill 4 (LF04), the stream flows over limestone and shale outcrop, but becomes an influent stream as water percolates into terrace (Upper Zone) deposits south and east of the landfill. The tributary west of Landfill 5 (LF05) and Site 12 (FT09) becomes effluent at Cody Drive where terrace deposits are relatively thin. Farmers Branch ultimately discharges to the Trinity River, located on the eastern boundary of Carswell AFB. The evaluation of ground-water flow at the Flightline Area suggests that the surface water bodies may receive ground-water inflow, and possibly contaminants associated with the ground water. A staff gage was installed in Farmers Branch (Figure 3-1) and professionally surveyed during the additional Stage 2 field activities. Synoptic ground-water and surface water-level measurements made in June 1990 were used to evaluate Upper Zone ground-water/surface water communication. A detailed discussion of this communication is provided in Section 4 of this report (Nature and Extent of Contamination).

Estimates of flow volume in Farmers Branch and the small tributary were made. Flow volumes were calculated by measuring the width and average depth of the stream(s), and then multiplying the resulting cross-sectional area by the estimated flow rate. The flow rate was estimated by measuring the length of time required for a floating object to travel a known distance. Estimated flow volumes at the time of sampling (April, 1990) were 6.0 cubic feet/second (cfs) for the four locations on Farmers Branch and 0.2 cfs for the small tributary to Farmers Branch. Water in the two ponds appeared stagnant at the time of sampling. Observed flow in Farmers Branch during field

activities was extremely variable, ranging from <5 to >100 cfs (following heavy rains).

3.3 Geology

Carswell AFB is located on the relatively stable Texas craton, west of the faults that lie along the Ouachita Structural Belt. No major faults or fracture zones have been mapped near the base. The regional dip of the rocks beneath Carswell AFB is between 35 and 40 feet per mile in an easterly to southeasterly direction. From youngest to oldest, the major geologic formations found in the Flightline Area of Carswell AFB are as follows: 1) Quaternary Alluvium, 2) Cretaceous Goodland Limestone, 3) Cretaceous Walnut Formation, 4) Cretaceous Paluxy Formation, 5) Cretaceous Glen Rose Formation, and 6) Cretaceous Twin Mountains Formation.

Subsurface geologic conditions in the Flightline Area were characterized using indirect methods (geophysical surveys) and direct subsurface sampling and lithologic logging during drilling operations. Most of the IRP activities focused on the Upper Zone. The Goodland/Walnut Aquitard and the Paluxy Aquifer in the Flightline Area were the deepest (oldest) units penetrated, and by only two monitor wells installed during the initial Stage 2 effort. The following subsections contain discussions of the geology in the Flightline Area.

3.3.1 Quaternary Alluvium

Quaternary alluvium, deposited by the Trinity River, is found at the surface throughout the Flightline Area site, as well as over most of the base. The alluvium consists of floodplain and fluvial terrace deposits of gravel, sand, silt, and clay that occur as a veneer on the eroded surface of the Goodland Limestone. The unconsolidated alluvial deposits and fill are referred to as the "Upper Zone," a term initially applied to similar alluvial deposits at AF Plant 4 (Hargis and Montgomery, Inc., 1983). The Upper Zone is a hydrogeologic unit at Carswell AFB that is a mixture of clay, silt, sand, and gravel of variable thickness and degree of saturation.

Drilling on the base indicates that the alluvial deposits (and fill) range from a few feet to greater than 45 feet of interbedded clay, silt, sand, and gravel. The irregular thickness of the alluvium is due to depositional events, stream channeling, and erosion. In general, silt and clay with variable amounts of sand and gravel occur at the land surface down to depths of five to 10 feet. Underlying the silt and clay is a sand and gravel unit that normally increases in grain size with increasing depth. These strata appear to be relatively continuous across the area of investigation, although coarse gravel deposits occur in limited areas generally east of the Fire Department Training Areas 1 (FT08) and 2 (FT09). The sand deposits are fine-grained to coarse-grained, tan to rust in color, and composed predominantly of quartz grains. Gravel is mostly limestone and shell fragments ranging in size from fine gravel to cobbles. A sand and gravel isopach map of the Flightline Area is presented in Figure 3-2.

During the most recent drilling activities in the Flightline Area, efforts were made to characterize the paleochannels (old stream channel patterns) believed to exist in the area. Examination of Figure 3-2 shows thick sand and gravel sequences, indicative of channel deposits, to occur east of Taxiway 197 and roughly paralleling White Settlement Road. Sand and gravel thicknesses greater than 20 feet occur in an approximately 800 foot-wide area, with White Settlement Road serving as the approximate median to the pattern. Additional evidence of the channel pattern is seen in the eroded nature of the bedrock in this area and the extensive limestone gravels (scoured bedrock). The gravels were deposited as channel lag deposits on the scoured upper surface of the underlying bedrock (Goodland/Walnut Formations).

3.3.2 Cretaceous Goodland Limestone and Walnut Formation

Underlying the alluvium are the Cretaceous-age Goodland and Walnut Formations. Both formations consist of interbedded, fossiliferous, hard limestone and calcareous shale, and are thus discussed together. The rock is fractured and there is considerable jointing and flaking, which gives the limestone a fractured appearance. These strata are generally dry, although small amounts of water are occasionally present in the shale and clay units.

The erosional surface of the bedrock is generally level across most of the Carswell AFB area, with a pronounced rise in the southwest portion of the base corresponding to the outcrop of limestone and shale. Table 3-1 shows the depth (and corresponding elevation) to bedrock (Goodland/Walnut Formation) at all drilling locations in the Flightline Area. Figure 3-3 contains a contour map of the elevation (MSL) of the top of the bedrock surface. The locally irregular topography of the top of the bedrock is characteristic of an erosional surface modified by fluvial processes, which is recorded by the overlying sequence of interbedded fluviatile gravel, sand, silt, and clay.

The thickness of the Goodland/Walnut Formations, as observed during the drilling of Paluxy wells P-1 and P-2 (Figure 3-2), is approximately 30-40 feet beneath the Flightline Area. However, because the top of the Goodland/Walnut Formations is an erosional surface, the thickness in isolated areas may be less than originally deposited. It has been reported that the Quaternary alluvium and the cretaceous Paluxy Formation are in direct contact at the eastern boundary of AF Plant 4, where the Goodland/Walnut Formations were completely eroded away (Hargis and Associates, 1985).

3.3.3 Cretaceous Paluxy Formation

Beneath the Goodland and Walnut Formations lies the Cretaceous-age Paluxy Formation, often referred to as the Paluxy Sand. The Paluxy Formation is the deepest unit penetrated in the Flightline Area during the IRP efforts. Regionally, the Paluxy Sand is divided into upper and lower sand members by an intervening shale unit. The sands in the upper part of the Paluxy are reported by drillers to be fine-grained and shaley. The lower sand member generally consists of two separate and distinct sand strata, but the individual sand beds do not maintain constant thickness or lithology over long distances. About one-half to three-fourths of the Paluxy is sand; the remainder consists of clay, sandy clay, shale, lignite, silicified wood fragments, and nodules of pyrite. In general, coarse-grained sand is in the lower part of the Paluxy which grades upward into fine-grained sand with variable amounts of shale and clay.

-- Not Determined

MSL - Mean Sea Level

Figure 3-3. Contoured Elevation of Bedrock Surface in Flightline Area, Carswell AFB, Texas

In the two Paluxy monitor wells (P-1 and P-2) installed during the initial Stage 2 effort, drilling progressed through the upper sand member to the intervening shale unit. The upper sand member ranged from 30 to 35 feet in thickness and consisted of varying amounts of sand, sandstone, clay, and shale. The shale unit separating the upper and lower Paluxy "sands" was encountered at approximately 105 feet, below land surface in both P-1 and P-2.

3.3.4 Cretaceous Glen Rose Formation

Underlying the Paluxy Sand is the Glen Rose Formation, which represents the seaward facies of part of the Twin Mountains Formation, being deposited simultaneously to the north. The Glen Rose was not penetrated during drilling in the Flightline Area, but typically consists primarily of calcareous sedimentary rocks (limestone) and some sands, clays, and anhydrite.

3.3.5 Cretaceous Twin Mountains Formation

The Twin Mountains Formation, with the Glen Rose Formation capping it, is the oldest Cretaceous-age formation reported in the vicinity of Carswell AFB. In ascending order, the Twin Mountains Formation is divided into the Sycamore Sand Member, the Cow Creek Limestone Member, and the Hensell Sand Member. The Twin Mountains Formation does not crop out in Tarrant County. The Twin Mountains Formation consists of a basal conglomerate of chert and quartz, grading upward into coarse- to fine-grained sand interspersed with varicolored shale.

3.3.6 Flightline Area Cross-Sections

Following the recent drilling activities at the Flightline Area, six geologic cross-sections were constructed, showing borehole lithologies (as well as the static water levels in the Upper Zone measured on 18 June 1990). A location map for the newly constructed cross-sections through the site is provided in Figure 3-4.

Two of the cross-sections (A-A' and B-B') are oriented roughly west-east and the remaining four are oriented roughly north-south (C-C' through F-F') through the site. All of the cross-sections intersect the relatively thick sand and gravel sequence observed at the site (Figure 3-2).

Cross-section A-A' (Figure 3-5) depicts the subsurface from the Landfill 3 (LF03) area to the area just east of Landfills 4 (LF04) and 5 (LF05) and the Waste Burial Area (WPO7). An important feature in this cross-section is the lack of sand and gravel in the borings completed in the Landfill 3 area. There is a steep incline in the upper surface of the bedrock (Goodland/Walnut Formations) between borings LF03-3E and LF05-15. Coincident with the lower bedrock elevation in the vicinity of LF05-15 is the appearance of relatively thick sands and gravels of the Upper Zone. This cross-section is oriented through the thickest sands and gravels encountered in the Flight-line Area (Figure 3-2). Boring locations from LF05-15 eastward all display a fining-upwards sequence in the Upper Zone deposits, which is consistent with alluvial deposition. The lower bedrock surface observed in the eastern half of the cross-section is probably the result of stream erosion, as rounded limestone and chert gravels (typical of channel lag deposits) rest directly on the bedrock surface. These deposits are believed to coincide with the location of a former channel (paleochannel) of what is now Farmers Branch.

In cross-section B-B' (Figure 3-6), another steep incline is observed in the bedrock topography between monitor well locations FT09-12A and FT09-12B. Paralleling the inclined bedrock surface is a steeply-dipping Upper Zone water table. Fining-upwards sequences are seen in all borings included in this cross-section, with gravels occurring on the eroded bedrock surface east of FT09-12A.

Shown in Figure 3-7 is cross-section C-C'. Gravels only occur in the middle area of the cross-section, with a relatively higher bedrock surface occurring in the northern and southern reaches of the section. The steeply inclined bedrock surface seen at location FT09-12A (B-B') is also reflected

Figure 3-6. Geologic Cross-Section B-B', Flightline Area, Carswell AFB, Texas

Figure 3-7. Geologic Cross-Section C-C', Flightline Area, Carswell AFB, Texas

on this cross-section at location LFO4-4A. Monitor well FT09-12C occurs at approximately the southern edge of the paleochannel deposits observed in the Flightline Area.

Cross-section D-D' is shown on Figure 3-8. Again, a relatively thick sequence of coarse-grained materials occurs through the middle portion of the cross-section. Southward from boring LFO5-12, the coarse-grained Upper Zone deposits thicken, with the thickest deposits occurring in the vicinity of LFO4-4F. Monitor well LFO4-4F is the only location on this section where gravels were found. Location LFO4-4B, like LFO4-4A (C-C'), is located on a relative high on the bedrock surface.

Geologic cross-section E-E' (Figure 3-9) shows the thickest sequence of Upper Zone sands and gravels occurring in the vicinity of LFO4-4G. Monitor well LFO4-4G occurs within the trend of the thickest Upper Zone sands and gravels observed in the Flightline Area. The trend axis is situated approximately on White Settlement Road.

The easternmost cross-section through the Flightline Area, F-F' (Figure 3-10), includes five newly installed ground-water monitor wells. Although monitor well boring LFO4-10 encountered the thickest sequence of Upper Zone coarse-grained sediments, the potentiometric surface (derived from water-level measurements taken on June 18, 1990) indicates ground-water flow toward the location of LFO5-19, rather than parallel to the depositional trend, as might be expected.

3.4 Hydrogeology

Five major hydrogeologic units exist beneath Carswell AFB. From shallowest to deepest they are: 1) an Upper Zone of unconfined ground water occurring within the alluvial terrace deposits associated with the Trinity River; 2) an aquitard of predominantly dry limestone of the Goodland and Walnut Formations; 3) an aquifer in the Paluxy Sand; 4) an aquitard of relatively impermeable limestone in the Glen Rose Formation; and 5) a major

aquifer in the sandstone of the Twin Mountains Formation. Only the first three units were investigated in the Flightline Area during the IRP, with the primary focus being on the Upper Zone. The Upper Zone was the only unit studied in this most recent Stage 2 (1990) effort. Figure 3-11 shows the general depth of occurrence and thickness of each of the major hydrogeologic units expected in the Flightline Area. Descriptions and properties of the hydrogeologic units are summarized in Table 3-2. The following subsections present the hydrogeologic characteristics of each unit based on field data and literature sources.

3.4.1 Upper Zone Aquifer

The Upper Zone ground water occurs within the alluvial deposits at Carswell AFB. Low permeability is typical of this alluvium because of the large amounts of clay and silt. However, there are zones of greater permeability in the sands and gravels of former channel deposits. Recharge to the water-bearing deposits is local, from rainfall and infiltration from stream channels and drainage ditches. The direction of ground-water flow is generally controlled by the bedrock topography of the Walnut Formation.

3.4.1.1 Ground-Water Occurrence and Flow

Table 3-3 shows the results of the Phase II Stage 2 (June, 1990) synoptic water-level survey. Figure 3-12 contains the resulting potentiometric surface map of the Upper Zone Aquifer. Ground-water flow in the Upper Zone is generally northeastward, toward Farmers Branch, a tributary to the West Fork of the Trinity River.

From the outlet of Farmers Branch from the underground aqueduct (which conveys the stream under the Flightline) the stream flows over bedrock at the Goodland/Walnut Formation until it flows into the Trinity River on the eastern boundary of Carswell AFB. The Upper zone ground-water flow through the Flightline Area, being generally northeastward, intercepts Farmers Branch in the northern and northeastern portion of the Flightline Area site. The

TABLE 3-2. GEOLOGIC FORMATIONS IN THE VICINITY OF CARSWELL AFB, TEXAS

System	Series and Group	Formation and Member	Thickness (ft)	Character of Rocks	Topographic Expression	Water-Bearing Properties
Quaternary	Recent and Pleistocene	Alluvium	0-45	Sand, gravel, clay, and silt.	Terrace and flood-plain deposits.	Small to moderate yields. Water unsatisfactory for use unless treated.
Cretaceous	Comanche Series Washita Group	Duck Creek Formation	0-90	Impure limestone and marl, which is blue when fresh and straw-colored when weathered. Fossiliferous with distinctive ammonites.	Bench topography produced by lower limestone unit. Upper marl forms slope separating the Duck Creek from Fort Worth limestone.	Small to moderate yields. Water unsatisfactory for use unless treated.
		Kiamichi Formation	0-40	Blue and brownish-yellow marl, thin limestone and sandstone flags.	Grassy slope separating scarps of Goodland and Duck Creek Formations.	Small to moderate yields. Water unsatisfactory for use unless treated.
Cretaceous	Comanche Series Fredericksburg Group	Goodland Limestone	0-130	Chalky-white fossiliferous limestone, and blue to yellowish brown marl.	Prominent glaring-white escarpment along streams.	Small to moderate yields. Water unsatisfactory for use unless treated.
		Walnut Clay	0-28	Shell agglomerate fossiliferous clay and limestone, sandy clay, and black shale.	Forms conspicuous escarpment and waterfalls in western Cross Timbers belt.	Not known to yield water to wells in Tarrant County.
		Paluxy Sand	140-190	Fine-grained sand, shale, sandy shale, lignite and pyrite.	Sandy soil, hummocky topography, heavily wooded with oaks.	Source of supply for most households, smaller cities, and some industries.
Cretaceous	Trinity Group	Glen Rose Limestone	250-450	Fine-grained limestone, shale, marl, and sandstone.	Not exposed in Tarrant County.	Sands yield small supplies to wells in Fort Worth and western Tarrant County. Water too highly mineralized east of Fort Worth.
		Twin Mountains Formation (formerly Travis Peak Formation)	250-450	Coarse to fine-grained sandstone, red shale, red and yellow clay at base.	Not exposed in Tarrant County.	Principal aquifer in Tarrant County. Yields large supplies for municipal and industrial purposes. Water in upper sands east of Fort Worth may be highly mineralized.

Figure 3-12. Potentiometric Surface Map of Upper Zone Aquifer, Flightline Area, Carswell AFB, Texas

Upper Zone sediments, which are up to 40 feet thick in areas west and southwest of Farmers Branch, either thin to their eventual disappearance at the stream or are exposed as sheer cliffs (cut-banks) near the stream. Field reconnaissance revealed Upper Zone ground water seeping from the face of the exposed banks.

The potentiometric surface map (Figure 3-12) includes water level information from both the ground water and the surface water (surveyed at six locations along Farmers Branch). Farmers Branch is shown to be a point of discharge for ground water, as the Upper Zone hydraulic gradient is shown to be toward the stream.

The area north of Farmers Branch in the Flightline Area has not been investigated. However, visual observation has shown the area to be relatively flat in the vicinity of the stream. Upper Zone deposits are probably thin in this area. With Farmers Branch being a zone of ground-water discharge in the Flightline Area, Upper Zone ground-water flow in the area north of Farmers Branch would locally be toward the stream.

3.4.1.2 Hydraulic Characteristics of Upper Zone Aquifer

Slug tests were performed in twelve Flightline Area wells (April, 1988) and an aquifer pumping test was conducted (June, 1990) to determine the hydraulic properties of the Upper Zone aquifer in the Flightline Area at Carswell AFB. The following section presents a discussion of the characteristics of the Upper Zone aquifer as determined from this testing. A more thorough description of the aquifer pumping test procedures and analysis is provided in Appendix F.

Slug Test Results

The ability of the Upper Zone alluvial deposits to transmit ground water was initially characterized based on the results of single-well aquifer tests (slug tests). These tests were performed as described in Section 2.2.5, and analyzed according to the Bouwer and Rice (1976) method.

The calculated hydraulic conductivity values ranged from 7.98×10^{-3} cm/sec (22.6 ft/day) at well LFO4-4D to 4.1×10^{-4} cm/sec (1.2 ft/day) at well LFO4-4A. The lowest calculated hydraulic conductivities were from wells known to be located outside the main pattern of channel deposits observed in the Flightline Area. The lowest calculated values were from test wells LFO4-4A and FTO-12A (Figure 3-12).

The main limitation on slug tests is that they are heavily dependent on a high-quality well intake (screened interval). If well development is inadequate, measured values may be highly inaccurate (decreased conductivities); conversely, if development is very thorough, the measured values may reflect the increased conductivities in the artificially induced gravel pack around the screen. In any case, slug tests usually provide aquifer parameter values that are fairly representative of a small volume of porous media in the immediate vicinity of the well. Aquifer pumping tests, however, usually provide measurements of aquifer parameters that are averaged over a much larger aquifer volume.

Aquifer Pumping Test Results

The data obtained during the June, 1990 Upper Zone aquifer pumping test were analyzed by several methods. Following field plotting of time-drawdown and distance-drawdown measurements, hand plotted observation well drawdown and pumping well recovery data were analyzed by the Jacob-Cooper method. In addition, a computer aquifer analysis program was used. The well hydraulics interpretation program used was WHIP™, which can simulate and analyze both drawdown and recovery tests.

The diagnostic procedures use semilog drawdown (Jacob-Cooper) analyses and Theis recovery analyses to obtain preliminary estimates of the transmissivity and storage coefficient. Theis curves are generated using these values and are graphically compared to the observed data. Portions of the generated curves can be "windowed" so only reliable data are used for the generation of final transmissivity and storage coefficient values. The

equations used in the Jacob-Cooper analysis of hand-plotted drawdown and recovery data is provided in Appendix F.

In addition to standard semilog and loglog plots, the effects of various time transformations on the data as well as first and second derivatives of the drawdowns were performed. Observing the derivative drawdown plots was useful for determining that portion of the test data displaying Theis behavior. Additionally, the Dupuit correction for water table conditions was applied to all computer analyses and the initial estimates of transmissivities and storage coefficients were optimized using an ordinary least squares fitting criterion. The Dupuit correction allows for the minimization of the irregularities inherent in field data and applies a more sophisticated mathematical approach to the calculation of transmissivities and storage coefficients.

Three different computer generated plots and analyses were determined to best represent the Upper Zone aquifer hydraulic properties of transmissivity and storage coefficient. These were the observation well (LF04-02) drawdown and recovery analyses and the pumping well (LF04-03) recovery analysis.

Seven additional monitor wells were measured for response to the pumping well during the test. These wells did not respond to pumping. Water level measurements taken in these wells were plotted and are included in Appendix F.

Table 3-4 shows the summarized results of the Flightline Area aquifer pumping test analysis. Both the pumping well (LF04-03) and the observation well (LF04-02) are completed in the generally west to east trend of relatively thick sands and gravels observed in the Flightline Area, and both wells are screened across the entire saturated thickness of the Upper Zone aquifer. The calculated hydraulic conductivity and transmissivity values fall within the range for clean sands and gravels (Freeze and Cherry, 1979) which

TABLE 3-4. SUMMARY OF UPPER ZONE AQUIFER PUMPING TEST RESULTS, FLIGHTLINE AREA, CARSWELL AFB, TEXAS
(JUNE, 1990)

Well Number	Type of Test Analyses	Distance From Pumping Well (ft)	Transmissivity	Hydraulic Conductivity	Storage Coefficient (Dimensionless)
LF04-02	Drawdown	50	9771 ft ² /day	835 ft/day (2.9 x 10 ⁻¹ cm/sec)	1.2 x 10 ⁻²
	Recovery	50	8260 ft ² /day	705 ft/day (2.5 x 10 ⁻¹ cm/sec)	
LF04-03	Recovery	Pumping Well	9501 ft ² /day	812 ft/day (2.9 x 10 ⁻¹ cm/sec)	
	Average Values		9177 ft ² /day	784 ft/day (2.8 x 10 ⁻¹ cm/sec)	1.2 x 10 ⁻²

is consistent with the lithology for the Upper Zone aquifer. The storage coefficient value calculated also falls within the range for clean, unconfined aquifers.

The hydraulic conductivity calculated from the pumping test analysis was significantly higher than that determined from prior slug testing. Based on the limitations of the slug testing discussed earlier, the aquifer pumping test results are more representative of the Upper Zone Aquifer characteristics.

3.4.2 Goodland/Walnut Aquitard

The ground water present in the alluvium is separated from the aquifers below by the low permeability limestones and shales of the Goodland Limestone and Walnut Formation. The aquitard is composed of moist clay and shale layers interbedded with dry limestone beds. Though the Formations are primarily dry, drillers in the area report that small amounts of water enter the borehole while drilling through the Walnut Formation, suggesting that ground water may be moving through the Walnut Formation along bedding planes (Hargis and Associates, 1985). The thickness of the Goodland/Walnut aquitard is approximately 30-40 feet beneath the Flightline Area at Carswell AFB. This thickness is based on two monitor wells drilled through the aquitard and completed in the Paluxy Aquifer during the initial Stage 2 study. However, the top of the aquitard is an erosional surface and erosion may have reduced the thickness of the limestone or eroded it entirely in isolated areas, (e.g., at AF Plant 4 beneath Building 189 along Grants Lane, the Goodland Limestone is completely absent and only three feet of the Walnut Formation are present (Hargis and Associates, 1985)).

3.4.3 Paluxy Aquifer

The Paluxy Aquifer, the areal extent of which is shown in Figure 3-13, is the shallowest bedrock aquifer underlying Carswell AFB. In the Carswell AFB area, water in the uppermost part of the Paluxy Formation would

naturally occur under confined conditions beneath the Goodland/Walnut aquitard (except where the aquitard has eroded away, as discussed above). However, extensive ground-water pumping in the Fort Worth area, including the City of White Settlement, has lowered the Paluxy Aquifer potentiometric surface below the top of the formation, resulting in unconfined conditions beneath the base. Water-level measurements taken in the Flightline Area Paluxy wells (P-1 and P-2, found the water level to be about five feet below the top of the formation, or about 75 feet below land surface. With the Paluxy Formation having an upper and lower sand member, and the lower member having larger grain size and higher permeability, most water wells are completed in the lower section of the Paluxy Aquifer.

Recharge to the Paluxy Aquifer occurs where the formation crops out west of Carswell AFB in the AF Plant 4 area. The Paluxy Formation also crops out north of the base in the bed of Lake Worth. The lake is a major recharge point for the aquifer and creates a potentiometric high in its vicinity. Regional ground-water flow within the Paluxy Aquifer is southeastward in the direction of the regional dip. At Carswell AFB, ground-water flow is influenced by recharge from Lake Worth, which creates a potentiometric high, and by ground-water withdrawals by the community of White Settlement. This drawdown results locally in a more southerly flow direction within the Paluxy Aquifer.

Transmissivities in the Paluxy Aquifer range from 1,263 to 13,808 gallons per day per foot (gpd/ft), and average 3,700 gpd/ft (CH2M Hill, 1984). The Paluxy Formation thickness ranges from 140 to 190 feet, averaging 160 feet in Tarrant County. The actual water-bearing thickness in the Carswell AFB area probably approximates the formation thickness, but the aquifer is separated into two distinct water-bearing zones, denoted as the upper and middle/lower Paluxy. In some cases, the middle and lower Paluxy are also separated by low-permeability layers. The Paluxy dips uniformly at a rate ranging from 35 to 40 feet per mile and averaging 37 feet per mile. It is encountered at increasing depths eastward, reaching a maximum depth of about 900 feet. During the Phase II Stage 1 Flightline Area investigation (Radian, 1986), short-term aquifer tests (pumping and recovery) were conducted in the

Paluxy Aquifer monitor wells P-1 and P-2. Recovery test data analysis indicates the transmissivity of the upper Paluxy is approximately 1750 gallons per day per foot (235 square feet per day).

3.4.4 Glen Rose Aquitard

Below the Paluxy Aquifer are the fine-grained limestone, shale, marl, and sandstone beds of the Glen Rose Formation. The thickness of the formation in the vicinity of Carswell AFB reportedly ranges from 250 to 450 feet. Although the sands in the Glen Rose Formation yield small amounts of water to wells in Fort Worth and western Tarrant County, the relatively impermeable limestone is an aquitard restricting water movement between the Paluxy Aquifer above and the Twin Mountains aquifer below.

3.4.5 Twin Mountains Aquifer

The Twin Mountains Formation is, geologically, the oldest formation used for water supply in the Carswell AFB area. The formation occurs approximately 600 feet below Carswell AFB. The thickness of the formation ranges from 250 to 430 feet.

Recharge to the Twin Mountains Aquifer occurs west of Carswell AFB, where the formation crops out. Ground-water movement is eastward in the downdip direction. Like the ground water in the Paluxy Aquifer, Twin Mountains ground water occurs under water-table conditions in the recharge area and becomes confined as it moves downdip. Transmissivities in the Twin Mountains Aquifer range from 1,950 to 29,700 gpd/ft and average 8,450 gpd/ft in Tarrant County. Hydraulic conductivities range from 8 to 165 gpd/ft² and average 68 gpd/ft² in Tarrant County (CH2M Hill, 1984).

4.0 NATURE AND EXTENT OF CONTAMINATION

The Carswell AFB IRP Phase II Stage 1 investigation (1984-85) detected concentrations of TCE and other halogenated hydrocarbons in the Upper Zone ground water in the vicinity of the flightline. In addition, concentrations of several metals exceeded federal drinking water standards in the ground water. During Stage 2 (1987-88), additional work was done to define the extent of the known contaminants present in the Flightline Area.

The primary objective of the addition (Modification 0004) to the original Stage 2 Statement of Work was to further characterize the nature and extent of various contaminants in the Upper Zone ground water beneath the Flightline Area. Specifically, the goal was to define the eastern and western boundaries of the known TCE plume under the Flightline Area, and to collect additional data such that a remedial action could be designed and implemented. In addition, an attempt to determine more conclusively the limits of the known inorganic contamination in the various Flightline Area sites was undertaken.

4.1 Summary of QA/QC

Carswell AFB ground water and surface water may be characterized by the primary data set generated from samples collected during April and May 1990. QA/QC results indicate this primary data set was generated under controlled analytical conditions. However, chemical concentrations should be qualified during site interpretation to incorporate uncertainty in terms of both measurement error and environmental variability. Qualifications to the data include:

- Laboratory blanks indicate a potential for false-positive results due to laboratory contamination for the following analytes. Maximum concentrations found in laboratory blanks are presented with specific analytes.

EPA 601	-	tetrachloroethene	0.17 $\mu\text{g/L}$,
		trichloroethene	1.3 $\mu\text{g/L}$,
EPA 325.3	-	chloride	1.5 mg/L,

SW6010	-	aluminum	0.53 mg/L,
		beryllium	0.0023 mg/L,
		copper	0.053 mg/L,
		nickel	0.021 mg/L,
		silver	0.051 mg/L,
		strontium	0.0047 mg/L,
		vanadium	0.025 mg/L,
		zinc	0.044 mg/L,
EPA 365.2		orthophosphate	0.012 mg/L,
SW7421		lead	0.0099 mg/L.

- Field blanks indicated a potential for false-positive results due to field contamination. Generally, field blanks contained very low level concentrations for common organics and inorganics. Natural sample results near laboratory and field blank concentrations may be considered false-positive results due to incomplete decontamination of sampling equipment or air-borne contamination.
- Variability due to environmental sources and measurement imprecision may be greater than expected for specific analytes. For instance, ICAP interference check samples indicated an interference for iron that caused 25% variability for check samples. Generally, measurement imprecision is greatest for results near the detection limit. As expected, relative variability (i.e., coefficient of variation (CV)) increases near detection limits even though absolute variability is very small.

The results of the recent ground-water sampling effort are discussed in the following subsections.

4.2 Results of Ground-Water and Surface Water Analyses

Ground-water samples from thirty-five wells were collected during April and May 1990 for laboratory analysis. Seven surface water samples were also collected. Since contamination was previously found to exist only in those wells screened in the Upper Zone Aquifer, all ground-water samples were collected from Upper Zone monitor wells. Figure 4-1 depicts the locations of all of the most recent water sampling sites at the Flightline Area. Each sample was submitted to Radian's laboratories for analysis of the organic and inorganic constituents listed in Table 4-1. Both organic and inorganic constituents exceeding EPA drinking water standards (Maximum Contaminant Levels, or MCLs) had been detected in the Flightline Area in past sampling efforts. An Informal Technical Information Report (ITIR) with analytical summary tables, QA/QC data, sample cross-reference tables and chain-of-custody forms for the recent ground-water investigation at the Flightline Area was provided to the U. S. Air Force HSD IRP Program Office in September 1990. Following is a brief summary of the quality assurance/quality control (QA/QC) results for most recent Carswell AFB ground-water sampling.

4.2.1 Ground-Water Contamination

As indicated in previous Flightline Area sampling efforts, TCE was the principal contaminant detected which exceeded EPA primary standards. The only other organic constituent found to exceed federal standards was vinyl chloride. Two organic compounds were detected in ground water with concentrations exceeding EPAs proposed MCLs; these included tetrachloroethene and cis-1,2-dichloroethene.

Four inorganic compounds exceeded federal standards in the most recent water sampling. Chromium was found in excess of the respective MCL in three monitor wells. Lead, arsenic and mercury were found in concentrations exceeding the respective MCLs in one well each. Iron and manganese were detected in numerous wells exceeding EPA Maximum Containment Level Goals (MCLGs). Other metals, such as calcium and silicon were common in ground-water samples.

Figure 4-1. Locations of 1990 Ground-Water and Surface Water Samples, Flightline Area, Carswell AFB, Texas

TABLE 4-1. SUMMARY LISTING OF ORGANIC AND INORGANIC ANALYTES,
FLIGHTLINE AREA, CARSWELL AFB, TEXAS

Organic Parameters	Inorganic Parameters	
	Heavy Metals	Non-Metals
1,1,1-Trichloroethane	Aluminum	Chloride
1,1,2,2-Tetrachloroethane	Antimony	Fluoride
1,1,2-Trichloroethane	Arsenic	Nitrate as N
1,1-Dichloroethane	Barium	Orthophosphate
1,1-Dichloroethene	Beryllium	Sulfate
1,2-Dichlorobenzene	Boron	Total Dissolved
1,2-Dichloroethane	Cadmium	Solids
1,2-Dichloropropane	Calcium	
1,3-Dichlorobenzene	Chromium	
1,4-Dichlorobenzene	Cobalt	
2-Chloroethylvinyl ether	Copper	
Bromodichloromethane	Iron	
Bromoform	Lead	
Bromomethane	Magnesium	
Carbon tetrachloride	Manganese	
Chlorobenzene	Mercury	
Chloroethane	Molybdenum	
Chloroform	Nickel	
Chloromethane	Potassium	
Dibromochloromethane	Selenium	
Methylene chloride	Silicon	
Tetrachloroethene	Silver	
Trichloroethene	Sodium	
Trichlorofluoromethane	Strontium	
Vinyl chloride	Thallium	
cis-1,2-Dichloroethene	Vanadium	
cis-1,3-Dichloropropene	Zinc	
trans-1,2-Dichloroethene		
trans-1,3-Dichloropropene		

Contamination detected in the ground water of the Flightline Area is limited to the Upper Zone Aquifer. The low permeability limestone of the underlying Goodland/Walnut aquitard underlies the Upper Zone Aquifer. No Flightline Area monitor wells are completed in the aquitard as past drilling in the Goodland and Walnut Formations has shown the formations to be non-water bearing. Ground-water samples from the Paluxy Aquifer, which underlies the Goodland/Walnut aquitard in the Flightline Area, have had no detections of contaminants. Therefore, the vertical extent of organic compound contamination in the Flightline Area corresponds to the upper surface of the Goodland/Walnut aquitard.

A detailed discussion of the pertinent organic and inorganic constituents and ground-water quality indicators follows.

4.2.1.1 Organic Ground-Water Contaminants

Table 4-2 summarizes the findings of the laboratory analyses for organic constituents in Flightline Area monitor wells, with respect to federal drinking water standards. TCE exceeded the MCL in 27 of the 35 wells sampled. Vinyl chloride exceeded federal MCLs in seven wells.

Tetrachloroethene (PCE) was detected in a total of six wells, exceeded proposed MCLs in three wells. Proposed MCLs were exceeded by cis-1,2-dichloroethene in 23 of the monitor wells in the Flightline Area. This compound was detected in 30 of 35 wells in the Flightline Area. Trans-1,2-dichloroethene, another isomer of dichloroethene, was also detected frequently in the Flightline Area but at significantly lower concentrations than the cis-isomer. The proposed MCL (100 $\mu\text{g/L}$) for the trans- isomer was never exceeded by Flightline Area water samples.

Following is a more detailed discussion of organic constituents detected in the ground water of the Flightline Area.

TABLE 4-2. SUMMARY OF ORGANIC GROUND-WATER SAMPLING RESULTS, SPRING 1990, CARSWELL AFB, TEXAS

Analytical Parameter	EPA Standards or * Proposed Standards (µg/L)	Range of Detection Limits	Range of Concentrations of Constituents Detected	Analyses for Constituent (No. of Wells)	Total Number of Samples

* EPA standards are designated: M - Maximum Contaminant Level (MCL), G - Maximum Contaminant Level Goal (MCLG), and P - Proposed Maximum Contaminant Level (PMCL).

Trichloroethene

Figure 4-2 depicts an isoconcentration contour map of the trichloroethene (TCE) plume as it was detected in the Spring, 1990 sampling effort in the Flightline Area. The concentration of TCE in the ground water reaches maximum levels in monitor wells LF04-4G and LF04-02, with detected values of 4400 and 4000 micrograms per liter ($\mu\text{g}/\text{L}$), respectively. The defined TCE plume has an aerial extent of approximately 50 acres, with the majority of the contamination underlying the base golf course. The limits of the plume are fairly well defined, except in the extreme eastern and western portions of the Flightline Area. In the west, a concentration of 2700 $\mu\text{g}/\text{L}$ was detected in monitor well LF05-01, with no accompanying downgradient well analyses to tightly enclose the downgradient contours. Therefore, the limit of the TCE plume extends west beyond this well. A detection of 1200 $\mu\text{g}/\text{L}$ TCE in monitor well LF05-5E, located hydraulically upgradient of Landfill 5, prevents the precise definition of the TCE plume in that upgradient edge. Evidence of "black staining" at 39.5 feet in the log of borehole LF05-15 may be further evidence of the upgradient extension of TCE contamination. The TCE plume appears to intersect Farmers Branch (Figure 4-1) in the northeastern portion of the Flightline Area.

Figure 4-3 is an thickness map of the sand and gravel deposits in the Flightline Area. The thick sand and gravel sequences evident on a east-west linear trend through the Flightline Area are thought to represent a paleochannel, which is the depositional remains of a former stream channel. Past reports have suggested that, due to the greater density of TCE with respect to water, coupled with the increase in available porosity and permeability, the contamination will tend to migrate preferentially along paleochannels filled with basal sands and gravels. When compared to the isoconcentration map of the TCE plume (Figure 4-2) this preferential migration is clearly evident, as the configuration of the plume and the zone of maximum concentrations closely resembles the location and configuration of the thickest Upper Zone sand and gravel sequences.

Figure 4-2. TCE Isoconcentration Contour Map, Flightline Area, Carswell AFB, Texas (Based on Spring, 1990 Water Sampling)

Figure 4-3. Sand and Gravel Isopach Thickness Map, Flightline Area, Carswell AFB, Texas

The center of the TCE plume appears to be bimodal and is located hydraulically downgradient from Landfill 4, with TCE concentrations above 3000 $\mu\text{g/L}$ covering an area of approximately 6.5 acres. The apex of the TCE plume does appear to have shifted since the last ground-water sampling effort, which took place in April 1988. Figure 4-4 represents an isoconcentration contour map of the results of the April, 1988 ground-water sampling. It is apparent when comparing the plume shape and locations in the April, 1988 isoconcentration map with that of the Spring, 1990 map that the plume has migrated in an easterly, hydraulically downgradient direction. In addition, the maximum concentration observed between the two sampling efforts has decreased, from 6400 $\mu\text{g/L}$ in April 1988 to 4400 $\mu\text{g/L}$ in the most recent analysis. The significance of this decrease with respect to the fate and transport of the contaminants in the ground water will be discussed in Section 5.0 of this report. While the migration and degradation of the plume is consistent with the physiologic and hydrogeologic setting of the Flightline Area and the nature of the contaminant, some degree of analytical variability is inherent between any two laboratory analyses occurring over time. It is understood that continued monitoring of the wells in the Flightline Area will be necessary to confirm trends in contaminant migration.

Multiple sources have been postulated for the organic contamination found in the subsurface in the Flightline Area. The disposal methods and types of waste material believed to be present at Landfills 4 and 5 (LF04 and LF05) are consistent with the types and amounts of contamination observed in downgradient wells. In addition, it is reasonable to assume that infiltration of flammable solvents associated with the fire training activities at site FT09 has contributed to the presence of contamination in the Upper Zone. Repeated evidence of TCE contamination in monitor wells located hydraulically upgradient of these sites suggests an additional upgradient source. Significant concentrations of TCE detected in monitor wells LF05-5E and LF05-5A (1300 $\mu\text{g/L}$ and 1200 $\mu\text{g/L}$), which are upgradient to LF05, strongly supports the assumption that a source exists upgradient of the known disposal areas in the vicinity of the flightline.

Figure 4-4. Contour Map of TCE Concentrations (> 1,000 µg/L) in Upper Zone Ground Water (April 1988), Flightline Sites, Carswell AFB, Texas

Air Force Plant 4 has been suggested in past reports as the probable upgradient source, but limited borehole and analytical data in the western and northwestern Flightline Area preclude this conclusion being drawn definitively. A TCE concentration of 2700 $\mu\text{g}/\text{L}$ in monitor well LF05-01, in the extreme northwestern portion of the Flightline Area site (Figure 4-2) indicates a significant source to the northwest. Further evidence supporting this conclusion is the contamination detected around site FT08. Monitor well FT08-11B was found to contain 35 $\mu\text{g}/\text{L}$ TCE. While this well is downgradient to the site, no contamination was detected in previous sampling efforts, and the site was not considered to be a contributor to the main TCE plume.

Contamination in the subsurface associated with FT09 was not considered to be part of the primary TCE plume in the RI/FS Stage 2 Report. Evidence cited included the lack of ground water in boreholes beneath the site and ground-water contamination being limited to monitor wells which might receive runoff from the site. During the most recent investigation, TCE contamination was detected in each of the three wells at the site. This, coupled with the fact that multiple sources have been recognized as contributors to the main TCE plume, suggest that the contamination detected at FT09 may be logically included in the principal TCE plume for the purpose of this report. As with other sites, the contamination present may have resulted from activities conducted at the site, or may be from an upgradient source.

Vinyl Chloride

With respect to EPA primary standards for drinking water, vinyl chloride was the second most dominant contaminant present in the Flightline Area, exceeding EPA limits (MCLs) in seven wells. Figure 4-5 illustrates an isoconcentration map of the vinyl chloride concentrations in the Flightline Area. Unlike the TCE plume, the vinyl chloride plume appears to be composed of several smaller zones of contamination, with the principal area being associated with Landfill 5 (LF05).

B100880

Figure 4-5. Vinyl Chloride Isoconcentration Contour Map, Flightline Area, Carswell AFB, Texas (Based on Spring, 1990 Water Sampling)

Each of the wells in the main plume in which the vinyl chloride was detected is immediately hydraulically downgradient of LF05. The maximum concentration of vinyl chloride detected in the Flightline Area was 170 $\mu\text{g/L}$ in monitor well LF05-5C. This well constitutes the apex of the main plume. Lesser amounts were detected in LF05-5B and WP07-10C, with 160 $\mu\text{g/L}$ and 49 $\mu\text{g/L}$, respectively. Vinyl chloride was also detected in this area in the April, 1988 ground-water sampling effort. None of the sampled monitor wells located hydraulically upgradient of LF05 contained vinyl chloride, suggesting LF05 is the source of the main Flightline Area vinyl chloride plume.

Four additional wells contained vinyl chloride above the EPA MCL. Well LF04-4C contained vinyl chloride at 13 $\mu\text{g/L}$, which is a higher concentration than was detected in the April 1988 sampling, in which 3.8 $\mu\text{g/L}$ was detected. This is the only well downgradient from LF04 in which vinyl chloride has been detected. Vinyl chloride was also detected in LF05-01 (100 $\mu\text{g/L}$), again suggesting a contaminant source upgradient from the Flightline Area. Since vinyl chloride may be a primary contaminant or one of the daughter products of TCE and multiple sources have been postulated for the contaminants present in the Flightline Area, it is difficult to pinpoint the exact source(s) of the vinyl chloride present in any individual well. The chemical inter-relationship between vinyl chloride, TCE and the other organic contaminants detected in the Flightline Area will be discussed in Section 5.0.

Tetrachloroethene

The presence of tetrachloroethene (PCE) was confirmed in six monitor wells in the Flightline Area. The EPA PMCL of 5.0 $\mu\text{g/L}$ was exceeded in three of these six wells. Due to the limited number of PCE detections in the Flightline Area ground water, an isoconcentration map was not prepared. Table 4-3 provides the laboratory results showing levels of PCE detected in each of the six monitor wells.

TABLE 4-3. SUMMARY OF RESULTS FOR GROUND-WATER SAMPLES WITH CONFIRMED DETECTED CONCENTRATIONS OF TETRACHLOROETHENE, SPRING 1990, CARSWELL AFB, TEXAS

Well Number	Tetrachloroethene Concentration ($\mu\text{g/L}$)
LF04-4C	3.1
LF05-02	0.55
LF05-19	17.0
FT09-12B	30.0
FT09-12C	8.1
FT09-12E	0.82

Two of the three wells found to exceed federal standards for PCE were in Site FT09 (FT09-12B and FT09-12C). FT09-12B had the highest confirmed level of PCE at 30 $\mu\text{g/L}$. PCE was not detected at this site during the April, 1988 sampling event. Since PCE can be a sister product of TCE, it is believed the appearance of PCE is related to the TCE plume. Therefore, for the purpose of this report, the PCE contamination detected in the Flightline Area will be treated in conjunction with the TCE plume. It is possible that the presence of PCE in the Flightline Area is more pervasive than what is depicted by the confirmed results. Unconfirmed (second column) PCE results of up to 1300 $\mu\text{g/L}$ were reported in ten wells, eight of which were in levels exceeding proposed EPA standards.

Total-1,2-Dichloroethene

Cis-1,2-dichloroethene (cis-1,2-DCE) was confirmed in thirty monitor wells in the Flightline Area, with concentrations ranging from 0.37 $\mu\text{g/L}$ to 730 $\mu\text{g/L}$. Trans-1,2-dichloroethene (trans-1,2-DCE) was confirmed in six wells, with concentrations ranging from 0.72 to 44.0 $\mu\text{g/L}$. Trans-1,2-DCE was detected only in wells in which cis-1,2-DCE was also detected. Because trans-1,2-DCE and cis-1,2-DCE are isomers, they will be considered together as part of the total-1,2-DCE plume.

Figure 4-6 illustrates an isoconcentration contour map for 1,2-DCE in the Flightline Area. As in the case of the TCE isoconcentration contour map, the apex of the plume is bimodal. The two 1,2-DCE nodes are located hydraulically downgradient of LF04 and LF05, respectively, and each is of the same relative magnitude of concentration. Further similarity to the TCE plume includes a lack of definition in the eastern and western margins of the plume. Monitor well LF05-01, in the extreme northwest portion of the Flightline Area, had a detected level of 1,2-DCE of 240 $\mu\text{g/L}$. This level of contamination, coupled with multiple confirmed detections of 1,2-DCE in wells immediately upgradient from sites LF04 and LF05, strongly support the presence of an upgradient contamination source. A confirmed detection of 540 $\mu\text{g/L}$ of 1,2-DCE

in monitor well LF04-04, in the southeastern portion of the Flightline Area, again makes it impossible to enclose contaminant contours in that area with confidence.

Other Organic Contaminants

Several other purgeable halocarbons were detected in the ground water in the Flightline Area (Table 4-2). These include the detection of 1,1,1-trichloroethane, 1,1-dichloroethane, 1,1-dichloroethene, 1,4 dichlorobenzene, chlorobenzene, chloroethane, and methylene chloride. None of these compounds were detected in levels exceeding current EPA standards.

The presence of methylene chloride was confirmed in two wells, LF05-5A and LF05-5C, at 64.0 and 90.0 $\mu\text{g/L}$, respectively. As in the case of PCE, numerous monitor wells had unconfirmed levels of methylene chloride detected. Unconfirmed concentrations ranging from 0.66 $\mu\text{g/L}$ to 120.0 $\mu\text{g/L}$ were detected in eight wells. Based upon the number of unconfirmed detections and the significant concentration of methylene chloride attained, it is conceivable that methylene chloride might be more prevalent than depicted on the basis of confirmed results only.

4.2.1.2 Inorganic Ground-Water Constituents

Four inorganic constituents, arsenic, mercury, chromium and lead, identified in the shallow Flightline Area ground water were found in excess of EPA MCLs. In addition, iron and manganese were found in concentrations that exceed EPA Maximum Contaminant Level Goals (MCLGs). Numerous other non-contaminant metals and inorganic ions were also detected in the ground water. Following is a discussion of inorganic contaminants detected in the shallow ground water of the Flightline Area.

4.2.1.3 Heavy Metals

Arsenic and mercury were each detected above MCL values in single monitor wells in the Flightline Area. Table 4-4 shows the metals detected for

TABLE 4-4. SUMMARY OF INORGANIC GROUND-WATER SAMPLING RESULTS, SPRING 1990, CARSWELL AFB, TEXAS

Analytical Parameter	EPA Standards (MCL/MCLG)* (mg/L)	Range of Detection Limits	Range of Concentrations of Constituents Detected	Total Number of Samples

*EPA standards are designated: M - Maximum Contaminant Level (MCL) and G - Maximum Contaminant Level Goal (MCLG).

which federal standards have been exceeded. As is evident from the table, arsenic, with an MCL of 0.05 milligrams per liter (mg/L), narrowly exceeded the limit (by 0.003 mg/L) in the well in which it was detected (LF05-02). Mercury exceeded federal standards by 0.0042 mg/L in FT09-12D. Arsenic was detected in concentrations above the MCL in eight monitor wells in the Flightline Area during the April 1988 sampling, mercury was not detected in this previous sampling.

Lead was found to exceed the federal standard of 0.05 mg/L in two monitor wells in the Spring 1990 sampling effort, as compared with detections exceeding MCLs in eight wells in the April 1988 sampling. Chromium exceeded the federal MCL of 0.05 in three wells in the Spring 1990 sampling, as compared with twelve in 1988. No two heavy metals were found above established MCLs in the same well. The lead contamination detected in monitor wells LF05-01 and LF05-14 exceeded federal standards by a maximum of 0.021 mg/L. Chromium was detected at a maximum of 0.15 mg/L above federal standards in monitor well FT08-11A.

Figure 4-7 depicts the locations of the seven wells in which MCLs for metals were exceeded. The random nature of the occurrence of the contaminants makes delineation of a specific source difficult. Multiple sources are possible for the metal concentrations as in the case of the organic contamination. In general, the metal concentrations detected in Flightline Area wells were down considerably from previous sampling events. Heavy metals such as cadmium and barium, detected in several wells at levels exceeding MCLs in the April 1988 sampling event, were not detected at levels exceeding federal standards in any wells in the Spring 1990 sampling effort.

As stated above, no two metals were detected in excess of federal standards in the same well. In addition, in each case where the federal standard was exceeded, the metal contamination indicated was from the 'Total' metal laboratory analysis and not the 'Dissolved' metal analysis. Total metal analyses are performed on unfiltered samples and as such may yield elevated metal results. Fine suspended material in the unfiltered sample can break

Figure 4-7. Location of Monitor Wells in Which EPA MCLs for Metals Were Exceeded, Flightline Area, Carswell AFB, Texas (Based on Spring, 1990 Water Sampling)

down during sample acidification and may release ions into the fluid medium. The dissolved metal analysis, performed on field-filtered samples, are considered more representative of the actual ground-water chemistry. In light of this, there is no evidence to support the existence of metal contamination in the Flightline Area at this time. In addition, the fact that a dissolved metal analysis was not performed during earlier sampling efforts, suggests that the previous data on metal contamination in the Flightline Area are inconclusive.

Metals such as iron and manganese were found to exceed MCLGs in most of the wells in the Flightline Area. However, the spatial distribution of these metals in both upgradient and downgradient locations probably reflects naturally occurring concentrations. Calcium and silicon were also pervasive, as would be expected where soils are composed primarily of clay, silica sand and weathered limestone.

4.2.1.4 Ground-Water Quality Indicators

Analysis of numerous anions and cations was performed on samples from each monitor well in the Flightline Area to aid in the determination of ground-water quality. These included:

- Calcium;
- Magnesium;
- Potassium;
- Sodium;
- Chloride; and
- Sulfate.

In addition, total dissolved solids (TDS) were analyzed. Table 4-5 lists the averaged concentrations for each analyte by site (in the Flightline Area), as well as the overall average for the entire Flightline Area, weighted by site. Also, a range of concentrations for each analyte (except potassium) is provided which is considered 'typical' for Tarrant County. Concentrations for each analyte are in milligrams per liter.

TABLE 4-5. SUMMARY OF GROUND-WATER QUALITY INDICATORS BY SITE, SPRING 1990,
CARSWELL AFB, TEXAS, WITH TYPICAL RANGE FOR TARRANT COUNTY

Site/Locality	Averaged Concentrations, mg/L							Total Dissolved Solids
	Calcium	Magnesium	Potassium	Sodium	Chloride	Sulfate		
FT08	150	7.8	3.3	70	22	87		680
FT09	140	5.4	3.1	23.8	13	64.2		484
LF04	136.6	6.6	3.3	29	25.5	61.3		565
LF05	167.7	11.3	5.3	28.9	33.9	65.2		782
WPO7	140	5.4	3.1	23.8	13	64.2		570
Flightline Area*	149.7	8.1	4.0	30.2	25.4	64.9		641.3
Tarrant County	1-114	0-11	--	141-670	14-650	21-579		381-1735

*Flightline Area averages were computed by the weighted probability method based upon the number of samples taken at each site.

At each site, calcium concentrations are elevated above the 'typical' range. In contrast, sodium concentrations fall uniformly below the given range. This is considered normal in ground water moving through lime-rich soils, such as those in the Flightline Area. All other ground-water quality indicator concentrations fall within the given range except the average chloride concentration in site FT09, which falls slightly below normal. Of significance is that a pronounced uniformity is evident between each of the sites in the Flightline Area, strongly suggesting an overall aquifer continuity, and further implying that the contaminants in the subsurface beneath each site are likely a part of the same contiguous plume.

4.2.2 Surface Water

Seven surface water samples were collected from the locations shown in Figure 4-8. Samples were collected from four locations along Farmers Branch, one from the small tributary to Farmers Branch, and one each from the two small ponds near the golf course maintenance headquarters. Surface water sampling sites were selected both to characterize the nature and extent of surface water contamination and to determine the relationship, if any, between surface water and ground water contamination. Surface water samples were also collected during the Phase II Stage 1 investigation (Radian, 1986).

4.2.2.1 Organic Contaminants

Table 4-6 summarizes the Spring, 1990 analytical results of organic constituents in surface water samples, with comparison to federal drinking water standards. Trichloroethene (TCE) was confirmed in all surface water samples, with federal MCLs being exceeded at five locations. Confirmed concentrations ranged from 1.8 $\mu\text{g}/\text{L}$ at LF05-S3 to 1400 $\mu\text{g}/\text{L}$ at LF05-S7. The elevated concentration at site LF05-S7 strongly suggests communication between the ground water and surface water at that location, as the concentration detected falls within the TCE isoconcentration contours generated for the ground-water analysis (Figure 4-2). Lower concentrations of TCE in samples collected from the upstream portion of Farmers Branch appear to be the result

*EPA standards are designated: M - Maximum Contaminant Level (MCL), G - Maximum Contaminant Level Goal (MCLG), and P - Proposed Maximum Contaminant Level (PCL).

of an upgradient contaminant source. This is particularly evident at surface water sample location LF05-S1, which is located where the underground aqueduct emerges following transporting Farmers Branch water under the runway area of Carswell AFB. Theoretically, surface water at this location has yet to be influenced by any Carswell AFB waste sites, as it is transported through a concrete conduit from the vicinity of Air Force Plant 4. Any contamination in a sample from this location is due to upgradient influences in the direction of Air Force Plant 4 further upstream. Nevertheless, surface water sampled at this location contained a TCE concentration of 39 $\mu\text{g/L}$, above the MCL (5 $\mu\text{g/L}$).

TCE was also confirmed in the Phase II Stage 1 investigation. Two rounds of samples were collected, with TCE being detected upgradient of LF04 in both rounds and immediately downgradient from LF045 in the second round. No detected levels of TCE exceeded federal MCLs. No relationship was established between surface water and ground-water TCE concentrations during the Stage 1 study.

Vinyl chloride was the only other organic contaminant detected in the surface water samples in excess of current federal standards during this investigation. Vinyl chloride was detected at two locations in the golf course ponds, LF05-S3 and LF05-S4. The MCL for vinyl chloride was exceeded in LF05-S3 where a concentration of 3.7 $\mu\text{g/L}$ was detected. Vinyl chloride was detected at the two locations where the lowest levels of TCE was detected, possibly suggesting a parent/daughter relationship. Vinyl chloride was also detected in Stage 1 surface water samples.

The remaining organic constituents confirmed at the surface water locations during the Spring 1990 sampling event were cis- and trans-1,2-dichloroethene (-DCE), which have proposed federal guidelines. As in the case of the ground-water samples, the cis-1,2-DCE isomer was more prevalent than the trans-1,2-DCE isomer in surface water samples, with the cis- isomer occurring at each of the seven sample locations. Concentrations of cis-1,2-DCE ranged from 3.1 $\mu\text{g/L}$ to 310 $\mu\text{g/L}$. Trans-1,2-DCE was confirmed in samples from two surface water locations, LF05-S2 and LF05-S3, with concentrations of

0.46 $\mu\text{g/L}$ and 0.66 $\mu\text{g/L}$, respectively. Of significance is that as in the case of the ground water, a direct relationship existed between TCE and cis-1,2-DCE with regards to the relative concentrations and the occurrence of each.

Surface water sample LF05-S7 had the highest confirmed concentration of both TCE and cis-1,2-DCE. The total-1,2-DCE concentration detected at this sample location also falls within the total-1,2-DCE isoconcentration contours generated for the ground-water analysis (Figure 4-6).

4.2.2.2 Inorganic Constituents

No heavy metals were detected in the surface water samples in excess of EPA MCLs. Barium was detected at each location in levels below the federal MCL of 1.0 mg/L. Lead is common, being detected at all locations except LF05-S4 and LF05-S7 at levels below the MCL for lead (0.05 mg/L). Minor amounts of arsenic (below the MCL) were detected at LF05-S3. These concentrations are not considered significant, since both barium and lead were common in levels below the MCLs in the ground-water samples. Arsenic concentrations at these levels were also common in the shallow ground water.

Both iron and manganese were found in excess of MCLGs in the surface water samples. Iron was found exceeding the MCLGs at four locations, with a maximum detection of 2.6 mg/L. Manganese was found exceeding the MCLGs at three locations, with the maximum level detected being 1.1 mg/L.

Water quality indicators were analyzed in the surface water samples. This was done both to assess the surface water quality and to attempt to clarify surface water/ground-water relationships. Indicators analyzed included:

- Total Dissolved Solids;
- Calcium;
- Magnesium;
- Potassium;
- Sodium;

- Chloride; and
- Sulfate.

Table 4-7 provides the averaged results for each of the water quality indicators for the surface water samples, as well as a range of concentrations for each analyte (except potassium) which are considered 'typical' for Tarrant County. In addition, the weighted averaged results for the same indicators are provided for the ground-water samples collected in the Flightline Area.

As is evident from the table, only sodium occurs outside the range provided for the indicators analyzed, being considerably below what would be considered a 'normal' concentration. This was also the case in the ground-water samples. The significant similarity between the averaged surface water results and the averaged ground-water results strongly supports the inter-relationship of the two water systems. This interrelationship has previously been discussed, and data generated at the site shows the tributary to Farmers Branch to be an influent stream in the Flightline Area. Only calcium differs slightly, with an averaged concentration in the ground water of approximately 45 mg/L greater than that of the surface water. This phenomenon is probably due to minor differences in the alkalinity of the two systems.

4.3 Summary of Findings

The main findings of the Flightline Area investigation with respect to the nature and extent of ground-water contamination are:

- Concentrations of TCE and vinyl chloride exceed federal primary drinking water standards in Upper Zone monitor wells in the Flightline Area.
- Multiple sources, including sites LFO4, LFO5, FT09, and Air Force Plant 4, have been postulated for the various organic contaminant plumes which occur in the Flightline Area.

TABLE 4-7. SUMMARY OF SURFACE WATER AND GROUND-WATER QUALITY INDICATORS, SPRING 1990, CARSWELL AFB, TEXAS, WITH TYPICAL RANGE FOR TARRANT COUNTY

Locality	Averaged Concentrations, mg/L						Total Dissolved Solids
	Calcium	Magnesium	Potassium	Sodium	Chloride	Sulfate	
Surface Water Samples	105.7	6.2	3	26.5	28.7	69.3	447
Flightline Area*	149.7	8.1	4.0	30.2	25.4	64.9	641.3
Tarrant County	1-114	0-11	*	141-670	14-650	21-579	381-1735

*Flightline Area averages were computed by the weighted probability method based upon the number of samples taken at each site.

- Some downgradient migration of the plume apex and a decrease in total TCE concentration may have occurred since the monitor well network was last sampled. However, continued monitoring will be necessary to verify this trend, which may also be affected by variability inherent in field and laboratory procedures.
- The extreme western edge of the Flightline Area TCE plume is as yet still undefined, but high levels of TCE and other contaminants detected in wells far upgradient of any known source areas strongly supports the existence of a significant upgradient source, possibly Air Force Plant 4.
- The extreme eastern limit of the TCE contaminant plume in the Upper Zone is also undefined.
- The vertical extent of contamination in the Flightline Area corresponds to the upper surface of the underlying Goodland/Walnut aquitard. Previous sampling of the two Paluxy Aquifer monitor wells have not revealed any contamination.
- It is probable that no heavy metal contamination exists in the Upper Zone Aquifer of the Flightline Area, as no concentrations exceeding federal drinking water standards were reported in the dissolved metal analyses.
- Both TCE and vinyl chloride were found in excess of federal standards in the surface water samples collected.
- Based upon the similarity between ground-water and surface water TCE concentrations, the tributary to Farmers Branch appears to be a zone of ground-water discharge.

- A pronounced similarity between surface water and ground-water quality indicators supports the existence of zones of communication between the two water systems.

5.0 CONTAMINANT FATE AND TRANSPORT

The purpose of this section is to define the interrelationship between the various contaminant plumes which exist in shallow (Upper Zone) ground water in the Flightline Area, and to discuss their migration and persistence. The transport and fate of contaminants in the Flightline Area and the potential for off-site or off-base migration is a function of the physical hydrogeologic conditions and the plume interrelationship.

Organic contaminants found in both the ground water and the surface water in the Flightline Area are the only hazardous waste constituents having a potential for off-site or off-base migration at levels of concern. No dissolved concentrations of inorganic constituents, specifically heavy metals, were identified in the ground water at levels exceeding federal primary drinking water standards. Risk assessments were performed earlier during the Phase II Stage 2 investigation, however these focused principally on airborne hazards.

The ground-water contaminant plume in the Flightline Area is best described in terms of trichloroethene (TCE). As stated in Section 4.0, TCE is the principal contaminant at the site, with detected concentrations of up to 4400 $\mu\text{g}/\text{L}$ and exceeding EPA's MCL (5 $\mu\text{g}/\text{L}$) in 27 wells. Other contaminants which are less widely distributed or occur in lower concentrations within the main Flightline Area plume include vinyl chloride, cis- and trans-1,2-dichloroethene, tetrachloroethene, and several other volatile organic halocarbon compounds.

5.1 Contaminant Persistence and Transformation

5.1.1 Background and Theory

The fate and persistence of the volatile organic contaminant plume in the Flightline Area is controlled by processes such as convection, contaminant adsorption and desorption on soil matrices, diffusion and dispersion, chemical and biological degradation, and volatilization and subsequent

resorption. Additionally, the nature of the contributing source(s), with regard to initial concentration and availability of contaminants, affects both fate and transport.

Diffusion and dispersion are chemical and mechanical processes whereby a contaminant tends to spread from the expected direction of transport governed by ground-water flow patterns. Diffusion depends on concentration gradients, and causes compounds to spread in the direction of lower concentrations. Dispersion is a function of mechanical transport, where physical mixing of the fluid media due to drag effects and pore channel tortuosity tend to cause some lateral solute spreading. Both of these phenomena contribute to dilution of specific contaminants within the body of the plume, but also result in the enlargement of the plume. Thus, these phenomena are factors in contaminant persistence and apparent retardation during transport.

Adsorption and desorption of a solute can be significant factors affecting the fate and transport of many types of contaminants. Compounds that are readily adsorbed onto grains of the aquifer material, and not readily desorbed are removed from the ground-water system and are not available for transport. Chemical partitioning by sorption can reduce effective transport by up to 100 percent. However, TCE is classified as a 'mobile' solute based upon its relatively low affinity to adhere to particles in the solid matrix. This classification is based on mobility, the value K_d , from the equation:

$$K_d = \frac{a_s}{a_w}$$

where: K_d = the soil-water distribution coefficient;
 a_s = the activity of the solute in the soil matrix; and
 a_w = the activity of the solute in the aqueous phase.

Mobility classes range from 'immobile' to 'very mobile', with TCE being in the second most mobile class out of five possible classes. In terms of solute transport, TCE has a higher activity in the aqueous phase, and hence will tend to both adsorb and desorb from soil grains with relative uniformity. Consequently TCE (and related daughter products) have a capacity for transport

which is only slightly retarded with respect to that due to the flow of ground water.

Mobility (K_d) is also a function of the concentrations of available solute, as the chemical activity of a solute will fluctuate based upon the chemical saturation of the parent media. One method of estimating K_d is based on site specific knowledge of TCE concentrations in the solid and aqueous phases. For the purpose of this report, TCE will be simply treated as a mobile solute, with adsorption and desorption being a factor in transport retardation.

As in the case of adsorption and desorption, TCE and other organic compounds may volatilize during transport and then be resorbed back into the aqueous phase. Chlorinated solvents are volatile compounds. Resorption of compounds following volatilization is based upon their ability to be adsorbed onto soil grains in the unsaturated zone and then be resorbed back into the ground water during periods of ground-water level fluctuation. Some compounds, such as 1,2-DCE and vinyl chloride, have low sorption coefficients, and consequently might be permanently removed from the ground-water system following volatilization. Because TCE is considered volatile and sorptive, some portion of the volatilized compound could re-enter the ground-water system during potentiometric (water level) rises. However, since the Upper Zone water table in the Flightline Area has not fluctuated significantly since 1985 when potentiometric surveys began, volatilization may possibly cause permanent removal of organic compounds from the ground water and therefore be a contributing factor in transport retardation. The degree of significance of this phenomenon is not known at the present time.

Chemical and biological degradation of the organic compounds in the Upper Zone ground water are potentially important factors in transport retardation in the Flightline Area. Tetrachloroethene (PCE), trichloroethene (TCE), cis- and trans-1,2-dichloroethene and vinyl chloride are all related by the chemical process of hydrogenolysis. From this reaction, PCE is broken down into a series of daughter products, ultimately yielding carbon dioxide

and water. This process is very common in nature, and may be biologically driven, as a form of biodegradation.

Figure 5-1 provides a summary of the three chemical and biological transformation pathways for the four principal organic contaminants in the Flightline Area. It is noteworthy that the half-lives for these pathways vary from tens of days to years, and the pathway to cis-1,2-DCE is generally favored. TCE and PCE formerly were both widely used in industrial solvents. The presence of PCE is probably from a primary source. It is doubtful that the PCE detected in the Flightline Area is from the breakdown of TCE with the limited amount of PCE detected, either a significant portion of the original concentration of this solvent has broken down into TCE or related daughter products, or the original volume of PCE was much lower than TCE.

Handwritten note: you proposed to define northern plume.

5.1.2 Flightline Area (Golf Course) Data

Figures 5-2, 5-3 and 5-4 present the isoconcentration maps generated for TCE, 1,2-DCE and vinyl chloride, respectively. This discussion of fate and transport of the ground-water contaminant plume does not consider the data north of the Farmers Branch underground aqueduct. This northern plume is not fully characterized and available data indicated that it is hydraulically separate and probably stems from a different source(s), than the plume underlying the golf course.

Based on the previous discussion and the knowledge that 1,2-DCE and vinyl chloride are not known to be used at the base, it is reasoned that the presence of 1,2-DCE and vinyl chloride are the result of the chemical and biological breakdown of TCE. By comparing the zones of highest concentrations in these three plumes, some scenarios can be suggested regarding the timing and continuity of the contaminant sources. Reviewing the figures:

- During the Spring 1990 ground-water sampling, the apex of the TCE plume was centered along White Settlement Road, roughly hydraulically downgradient from Landfill 4 (LF04);

Figure 5-1. Potential Degradation Products and Reaction Mechanisms for Reduction of Chlorinated Ethanes and Ethylenes

Figure 5-3. Total-1,2-DCE Isoconcentration Contour Map, Flightline Area, Carswell AFB, Texas (Spring, 1990)

- A small irregular area of elevated TCE concentrations is present around monitor well LF05-14, downgradient from Landfill 5 (LF05);
- The 1,2-DCE (Figure 5-3) plume has highest concentrations immediately downgradient from LF05 and LFO4, with gradually decreasing concentrations downgradient of both landfills; and
- Finally, vinyl chloride is present almost exclusively hydraulically downgradient of LF05.

If 1,2-DCE and vinyl chloride concentrations detected in the ground water are directly the result of TCE degradation, then a comparison of the locations and concentration distributions within the plumes suggests an earlier introduction of TCE from LF05 into shallow ground water, with significant degradation to 1,2-DCE and vinyl chloride having occurred, and a later release from LFO4, where time has allowed only degradation to 1,2-DCE to occur. Furthermore, the overall release of contaminants from LF04 may have declined somewhat with time, as concentrations of TCE immediately downgradient from LF04 have declined since the previous sampling in April 1988.

The fact that cis-1,2-DCE is favored in the chemical breakdown of TCE supports the hypothesis that all of the 1,2-DCE present in the Flightline Area results from TCE degradation. As stated earlier, cis-1,2-DCE is present in concentrations far exceeding trans-1,2-DCE, and the compound was detected in five times as many wells. This would be expected if the two compounds were daughter products of TCE, as the breakdown pathways of TCE to trans-1,2-DCE or 1,1-DCE are considered minor. However, all of the conclusions in this section must be viewed with caution. Review of the historical ground-water chemical data from the Flightline Area indicates considerable variability in concentrations of volatile organic compounds over short periods (i.e., between monthly sampling rounds). These fluctuations are unlikely to be related to longer-term degradation patterns.

5.2 Contaminant Migration Pathways

Ground water and surface water at the Flightline Area appear to be in hydraulic communication, based on results of synoptic water level measurements, and supported by chemical analyses from surface-water and ground-water samples. The water quality indicator compounds in each system were similar, and the detected contaminants occurred in similar proportions. Ground-water contaminants TCE and 1,2-DCE were also detected in each surface-water sample. In addition, as discussed in Section 4.0, the concentrations of TCE and 1,2-DCE detected at surface-water sampling points were consistent with contaminant concentrations at nearby ground water sampling locations. Each of these points of conformity supports the notion of a hydraulic connection between ground water and surface-water systems. Furthermore it is apparent that the tributary to Farmers Branch is a point of ground-water discharge which ultimately contributes contaminated water into Farmers Branch. To simplify the discussion of contaminated migration, the migration of the contaminant plume will be described individually in terms of the ground-water and surface-water systems.

5.2.1 Transport in Ground Water

Comparison of Figures 5-2 (Spring 1990) and 5-5 (April 1988) showing TCE concentrations in ground water suggests that some migration of the TCE plume has occurred. Recognizing that the interpreted isoconcentration contours can partially reflect sampling and analytical variabilities, the apex of the plume, once centered on monitor well WP07-10B, is now centered between monitor wells LF04-4G and LF04-02. If this change is attributed to advection, it represents a migration distance of dissolved TCE of several hundred feet.

Data generated from Upper Zone Aquifer pump testing, performed in June 1990, and water-level data suggest the average ground-water flow rate in the Upper Zone is approximately 9 feet per day. This is based on a hydraulic conductivity of 785 feet/day and an hydraulic gradient of 0.0035. Since the hydraulic conductivity derived from aquifer testing falls in the suggested

Figure 5-5. Isoconcentration Contour Map of TCE Concentrations from April 1988 Upper Zone Ground-Water Sampling, Flightline Area, Carswell AFB, Texas

range for clean sands to gravels (Freeze and Cherry, 1979), a porosity of 30% was assumed. The estimate for the average ground-water flow velocity is derived from a simplification of Darcy's Law:

$$\bar{v} = \frac{Ki}{\phi}$$

where: \bar{v} = average ground-water flow velocity
 k = hydraulic conductivity of Upper Zone Aquifer
 (average 2.8×10^{-1} cm/sec or 785 feet/day),
 i = hydraulic gradient (0.0035) in the Upper Zone; and
 ϕ = estimated porosity of the Upper Zone deposits (0.30).

Based on this calculation, the position of the TCE plume is migrating approximately an order of magnitude slower than ground water flow. This is not unusual based upon the physical, chemical and biological factors which affect the solute mobility with respect to ground water, as previously discussed in Section 5.1.

The main contaminant plume appears to be migrating in a direction which is generally consistent with the direction of ground-water flow. Figure 5-6 shows a potentiometric surface map generated from the June 1990 water level survey, with the corresponding ground-water flow directions indicated. The dominant direction of migration closely follows the orientation of the thickest accumulation of sand and gravel in the Flightline Area (Figure 5-7). A comparison of the sand and gravel isopach map with the recent TCE plume map (Figure 5-2) clearly indicates that plume migration may be preferentially influenced by the increased porosity and hydraulic conductivity of the sand and gravel interval.

The direction of plume migration appears to be roughly parallel to White Settlement Road. The maximum extent of the plume in that direction is unknown, as samples from the two most easterly monitoring wells, LF04-04 and LF05-19 had detected levels of 2700 and 1300 $\mu\text{g/L}$ TCE, respectively, in the Spring 1990 sampling event. However, given historical observations and at the

Figure 5-6. Upper Zone Aquifer Potentiometric Surface Map (June, 1990), Flightline Area, Carswell AFB, Texas

Figure 5-7. Sand and Gravel Isopach Thickness Map, Flightline Area, Carswell AFB, Texas

estimated rate of contaminant transport, the apex of the contaminant plume would not be expected to migrate beyond the general locations of LF04-04 and LF05-19 within the next several years.

It is along this vector of migration that the plume most directly intersects the unnamed tributary to Farmers Branch. Both TCE and 1,2-DCE were found in high concentrations in surface-water sample LF05-S7 (collected from the small tributary (Figure 5-2)). At this locality, contaminated ground water appears to discharge directly into the surface water, which in turn flows into Farmers Branch. Because upstream flow in this small tributary intermittently disappears into the subsurface (from the southeast corner of LF04 to just upstream of LF05-S7), it is likely that the water at the sampled location is almost entirely the result of ground-water discharge. However, as evident from Figure 5-2, the tributary is not a ground-water flow boundary and thus all ground-water contamination in the vicinity of the small tributary is not 'captured' or diverted as surface-water flow. This conclusion is also supported by the finding of elevated concentrations of TCE and 1,2-DCE in wells hydraulically downgradient of the tributary. This is most evident on the south side of White Settlement Road, where TCE was detected at 2700 $\mu\text{g/L}$ in monitor well LF04-04, east (downgradient) of the small tributary. While potentiometric contours are interpreted to wrap around the tributary at LF05-19, migration of a portion of the contaminants continues in an east-south-easterly direction past the location of LF04-04.

The more northerly component of the TCE plume migration, which parallels the direction of ground-water flow, is toward Farmers Branch. Farmers Branch was sampled at four locations in the Spring 1990 sampling event. While the dominant ground-water flow is in the direction of Farmers Branch, the main contaminant plume has not indicated a strong preferential migration in that direction. TCE concentrations of 1.8 and 4.5 $\mu\text{g/L}$, found in surface-water samples collected in two small ponds located immediately north of monitor well LF04-14, appear to approximate the northerly extent of the TCE plume. Any potential contaminant migration to the east of these ponds would be intercepted by Farmers Branch. Since no samples have been collected on the opposite side (northern) of Farmers Branch, it is uncertain whether the ground

water on that side of the stream is contaminated. Contamination in Farmers Branch and the tributary to Farmers Branch is discussed in Section 5.2.2, below.

TCE has not been encountered as a dense non-aqueous phase liquid (DNAPL) in monitor wells installed in the Flightline Area, however, if DNAPL does exist, it would tend to sink due to the difference in specific gravity between TCE and water. Figure 5-8 depicts a structural contour map drawn on the top of the Goodland/Walnut Formation, which is the aquitard beneath the Upper Zone and considered to be the limit of vertical contamination. It is probable that migration of any DNAPL would be influenced by the configuration of the top of the aquitard. The solubility of TCE in water is 1100 mg/L, and based on the analyses received from the various sampling efforts, concentrations sufficient to warrant the presence of TCE as a DNAPL are not expected in the Flightline Area. While TCE may have been released in a pure phase from one of the source sites, immediate and extensive dilution occurs as the leachate enters the ground water, as reflected in the TCE concentrations detected in downgradient wells. Preferential migration (following the configuration of the aquitard) in the Flightline Area is not expected to occur with the solvent concentrations encountered, as the difference in density between the contaminated solution and the ground water is not significant.

5.2.2 Transport in Surface Water

Surface-water contamination in the Flightline Area is affected by both the extent and migration of the ground-water plume, and by the variations in the discharge and velocity of the two principal surface-water bodies occurring in the area. Farmers Branch, which ultimately flows off-site, had variable concentrations of TCE and 1,2-DCE based on the sample location. In addition, the Farmers Branch is fed by the small tributary draining the southern portion of the study area, from which the most highly contaminated surface-water samples were collected. As a consequence, surface-water contaminant transport will be considered exclusively in terms of Farmers

Branch. For the purpose of this discussion, Farmers Branch will be divided into three reaches, each with a different contaminant input and potential for contaminant migration.

Figure 5-9 shows the location of the surface-water sampling sites and identifies the three divided reaches of Farmers Branch. The first reach of Farmers Branch includes the upstream portion from the end of the concrete underground aqueduct to the waterfall adjacent to the golf course ponds. This section of Farmers Branch is not influenced by the main TCE plume, as the golf course ponds are located approximately at the northern edge of the plume. TCE was detected, however, in the two samples collected in this reach. The TCE in these samples is believed to be the result of the upgradient source previously mentioned in this report. While the TCE detected in this portion of Farmers Branch is significantly above federal primary drinking water standards, it is probable that contamination observed in this reach does not contribute greatly to the overall observed downstream concentration of TCE. It is probable that a large percentage of all volatile organic contaminants (including TCE and 1,2-DCE) are stripped from the stream by volatilization as the stream crosses the waterfall which separates the first reach from the second reach.

The second designated reach of Farmers Branch includes that portion which is downstream of the waterfall and upstream of the intersection of Farmers Branch and the small tributary. In this reach, the main TCE plume appears to intersect the stream, and both TCE and 1,2-DCE contamination was detected in sample LF05-S5. However, even with continued migration of the main TCE plume in the direction of Farmers Branch, the concentration detected in this segment of the stream is not expected to increase significantly, and hence is not expected to be a major contributor to downstream contamination. The reason for this is the Upper Zone Aquifer outcrops in a broad cutbank of Farmers Branch across the entirety of this reach, and the ground water is therefore not in direct communication with the stream. Instead, water from the Upper Zone emanates from a series of seeps along the cutbank, and percolates down the face of the cutbank into a series of pools which are located

Figure 5-9. Surface Water Sampling Points and Three Divided Reaches of Farmers Branch, Flightline Area, Carswell AFB, Texas

on limestone bedrock of the Goodland/Walnut Formation. As in the case of the upper reach, this allows for significant volatilization and evapotranspiration to occur, and would consequently strip most of the contaminants from the water prior to any possible mixing with surface water from Farmers Branch. It is likely that minor amounts of contaminants from both reaches may migrate downstream to the third reach.

Significant concentrations of TCE and 1,2-DCE in the ground water (on the order of 1300 $\mu\text{g/L}$ and 280 $\mu\text{g/L}$, respectively) are discharging as surface water in the vicinity of surface-water sample location LF05-S7. This water, in turn, discharges directly into Farmers Branch in the third reach, and constitutes the principal pathway for off-site and off-base migration. Since the tributary to Farmers Branch is considered equivalent to a direct discharge of the main TCE plume, the discharge of the tributary and also Farmers Branch were calculated to determine the effects of dilution as the two bodies intersect. This was done using the simple relationship:

$$Q = vA$$

where: Q = discharge
v = velocity
A = cross-sectional area

Applying this equation to values obtained in the field, the slow moving tributary had a calculated discharge of approximately 0.2 cubic feet per second (cfs) or about 129,000 gallons per day (gpd). In contrast, at the time of field measurement, the discharge of Farmers Branch was approximately 6.0 cfs, or about 3,900,000 gpd. This translates into a dilution factor of about 30, suggesting that contaminant concentrations in Farmers Branch would be thirty times lower than those occurring in the tributary. Surface-water sampling results confirmed this, as the TCE concentrations between samples LF05-S7 and LF05-S6 (1400 $\mu\text{g/L}$ and 43 $\mu\text{g/L}$) appear diluted by a factor of 33 and 1,2-DCE concentrations between the same two locations (310 $\mu\text{g/L}$ at LF05-S7 and 8.4 $\mu\text{g/L}$ at LF05-S6) appear diluted by a factor of 37.

It may be concluded that as the ground-water plume continues migrating to the east, the concentrations of organic contaminants detected in the small tributary, and hence in Farmers Branch, may increase proportionately. However, plume degradation by physical, chemical and biological factors may result in transport of contaminants off-site remaining fairly constant over the next few years. Currently, TCE migration off-site in Farmers Branch is estimated at 45 $\mu\text{g/L}$ and 1,2-DCE migration off-site is estimated at 8.4 $\mu\text{g/L}$. There are insufficient data available to estimate the concentration of these contaminants in reaches of Farmers Branch outside the Flightline Area. However, volatilization will reduce the organic contaminant content of Farmers Branch before its ultimate discharge into the Trinity River.

GLOSSARY OF DEFINITIONS, NOMENCLATURE, AND UNITS

AA	atomic absorption
AFB	Air Force Base
Alluvium	stream-deposited sediment; predominantly clay, silt, sand, and gravel
Aquifer	geologic unit capable of storing and transmitting significant quantities of ground water
Aquitard	geologic unit impervious to ground water which acts to contain ground water within an adjacent unit
ARAR	Applicable or Relevant and Appropriate Requirement
Artesian	term applied to ground water confined under hydrostatic pressure
BLS	below land surface
DOD	U.S. Department of Defense
ECD	electron capture detector
EICP	Extracted Ion Current Profile
EPA	U.S. Environmental Protection Agency
Evapotranspiration	loss of water from the soil both by evaporation and by transpiration to growing plants
Extraction	method for mobilizing contaminant species from a solid matrix prior to analysis
FDTA	Fire Department Training Area
FS	feasibility study
GC	gas chromatography
GC/HSD	gas chromatography/halide specific detector
GC/MS	gas chromatography/mass spectroscopy
GFAA	graphite furnace atomic absorption spectroscopy

GLOSSARY OF DEFINITIONS, NOMENCLATURE, AND UNITS (Cont.)

gpd	gallons per day
gpm	gallons per minute
Hydraulic Conductivity	a coefficient of proportionality describing the rate at which water can move through a permeable medium
IRP	Installation Restoration Program
MCL	Maximum Contaminant Level
MS	mass spectroscopy
MSL	mean sea level
MS/MSD	Matrix Spike/Matrix Spike Duplicate
NCP	National Contingency Plan
OEHL	Occupational and Environmental Health Laboratory
OVA	organic vapor analyzer
O&G	oil and grease
PCB	polychlorinated biphenyl
PID	photoionization detector
piezometric/potentiometric surface	an imaginary surface representing the static head of ground water defined by the level to which water will rise in a well
PMCL	proposed maximum contaminant level
ppb	parts per billion
ppm	parts per million
QAPP	Quality Assurance Program Plan
QA/QC	Quality Assurance/Quality Control
RI/FS	Remedial Investigation/Feasibility Study
SOW	State of Work

GLOSSARY OF DEFINITIONS, NOMENCLATURE, AND UNITS (Cont.)

spike	a known amount of a compound added to a sample and analyzed to determine the accuracy of analysis
SW-846	EPA test methods for evaluating solid wastes, physical and chemical methods
TCE	trichloroethene
TDS	Total Dissolved Solids
TOC	Total organic carbon
TOX	Total organic halides
TPM	Technical Program Manager
Transmissivity	the rate at which water is transmitted through a unit width of an aquifer or confining bed under a unit hydraulic gradient.
USAF	United States Air Force
USAFOEHL	United States Air Force Occupational and Environmental Health Laboratory
USDA	United States Department of Agriculture
USGS	United States Geological Survey
VOC	volatile organic compound
water table	the elevation of the ground water surface in an unconfined aquifer

GLOSSARY OF DEFINITIONS, NOMENCLATURE, AND UNITS (Cont.)

<u>Multiplication Factor</u>	<u>Prefix</u>	<u>Symbol</u>
1,000,000,000,000,000,000=10 ¹⁸	exa-	E
1,000,000,000,000,000=10 ¹⁵	peta-	P
1,000,000,000,000,000=10 ¹²	tera-	T
1,000,000,000,000=10 ⁹	giga-	G
1,000,000,000=10 ⁶	mega-	M
1,000,000=10 ³	kilo-	k
100=10 ²	hecto-	h
10=10 ¹	deka-	da
0.1=10 ⁻¹	deci-	d
0.01=10 ⁻²	centi-	c
0.001=10 ⁻³	milli-	a
0.000 001=10 ⁻⁶	micro-	u
0.000 000 001=10 ⁻⁹	nano-	n
0.000 000 000 001=10 ⁻¹²	pico-	p
0.000 000 000 000 001=10 ⁻¹⁵	fento-	f
0.000 000 000 000 000 001=10 ⁻¹⁸	atto-	a

ppm(parts per million) = mg/kg, ug/g, ng/mg, pg/ug, mg/L, ug/mL, ng/uL

ppb (parts per billion) = ug/kg, ng/g, pg/mg, ug/L, ng/mL, pg/uL

ppt (parts per trillion) = ng/kg, pg/g, fg/mg, ng/L, pg/mL, fg/uL

APPENDIX A

Lithologic Logs

(Previous Lithologic Logs may be found in CH2M Hill (1984),
Radian (1986), and Radian (1988))

DRILLING LOG	RADIAN CORPORATION	INSTALLATION: CARSWELL AFB, TX	SHEET 1 OF 2 SHEETS
1. PROJECT: CARSWELL AFB, IRP PHASE II STAGE 2		7. TOTAL DEPTH OF HOLE: 40.1 ft BGL	
2. LOCATION: Flightline Area		8. DATUM FOR ELEVATION SHOWN: sea level	
3. DRILLING AGENCY: Environmental Drillers, Inc.		9. MANUFACTURER'S DESIGNATION OF DRILL: Mobile Drill B-61	
4. HOLE NO.: LF04-01		10. NO. OF SAMPLES TAKEN: 17	
5. NAME OF GEOLOGIST: S. E. Fain		11. ELEVATION GROUND WATER: 600.26 ft MSL (6/18/90)	
6. COORDINATES OF HOLE: X: 2019579.19 Y: 397653.57		12. DATE HOLE ESTABLISHED: 3/23/90	
		13. SURFACE ELEVATION: 626.50 ft MSL	
		14. BACKGROUND:	
		15. MEASURING POINT ELEVATION: 629.24 ft MSL	

Depth (Ft.)	Graphic Log	Blow Count	Soil Class/Code	Visual Description	Remarks
0			U/CLLR	Clay: Dark brown, slightly silty, very stiff, damp minor small gravel.	Full recoveries unless noted.
2			U/CLLR	Clay: As above, 5 - 10% calcareous material (nodules, mottling).	
4			U/CLLR	Clay: Orange/Brown, silty, minor fine sand, calcareous material ~ 10 - 20% of sample, very stiff.	Could not cut with knife.
6			U/CLLR	Clay: As above, mottling of various colors is disturbed looking.	
8			U/CLLR	Clay: As above, ~ 20% green silty clay.	Boring does not appear to encounter fill material (Like LF05-02).
10			U/CLLR	Clay: Orange/brown with greenish mottling, silty, sandy, ~ 1% calcareous material, firm.	
12.3			U/SDSM	Sand: Orange/brown, very clayey and silty; very fine to fine grained, bedding (horizontal) evident, damp; Clays occur mainly in 2 - 4 in. seams - every foot.	
14			U/SDSM	Sand: As above.	
16			U/SDSM	Sand: Burnt orange, fine grained, slightly clayey, damp, quartzose, Clay occurs as thin seams.	1.2 ft. Recovery
19			U/SDFN	Sand: Tan, fine grained, loose, >95% quartz, damp; oxidation stained laminae 21.5 - 22 ft.; 0.4 ft. clay seam 21.1 - 21.5 ft.	4.2 ft Recovery.

DRILLING LOG	RADIAN CORPORATION	INSTALLATION: CARSWELL AFB, TX	SHEET 2 OF 2 SHEETS
1. PROJECT: CARSWELL AFB, IRP PHASE II STAGE 2		7. TOTAL DEPTH OF HOLE: 40.1 ft BGL	
2. LOCATION: Flightline Area		8. DATUM FOR ELEVATION SHOWN: sea level	
3. DRILLING AGENCY: Environmental Drillers, Inc.		9. MANUFACTURER'S DESIGNATION OF DRILL: Mobile Drill B-61	
4. HOLE NO.: LFD4-01		10. NO. OF SAMPLES TAKEN: 17	
5. NAME OF GEOLOGIST: S. E. Fain		11. ELEVATION GROUND WATER: 600.26 ft MSL (6/18/90)	
6. COORDINATES OF HOLE: X: 2019579.19 Y: 397653.57		12. DATE HOLE ESTABLISHED: 3/23/90	
		13. SURFACE ELEVATION: 626.50 ft MSL	
		14. BACKGROUND:	
		15. MEASURING POINT ELEVATION: 629.24 ft MSL	

Depth (Ft.)	Graphic Log	Blow Count	Soil Class/Code	Visual Description	Remarks
24			U/SDFN	Sand: As above, heavily oxidized 24 - 25 ft.	
25			U/CLLR	Clay: Brown, gray in 1 - 2 in. seams, oxidation mottling, sandy (fine grained), cohesive, moist; getting sandier past 28 ft., wet at 28.5 ft.	
29			U/CLLR	Clay: Brown, very sandy, saturated, slightly cohesive; sand is very fine to fine grained, ~ 30 - 40%; 31 - 32 ft. clay, little sand; 32 - 34 ft. sand with minor clay.	W. L. Measured down augers at 29.6 ft. BLS, W. L. after completion = 27.5 BLS, 3.6 ft. Recovery.
32			U/SDSM	Sand: Burnt orange (heavily oxidized), fine to medium grained, slightly clayey, slightly cohesive. Increasing coarseness and 10 - 20% gravels (small) 33 - 34 ft.	
34			U/SDGR	Sand and Gravel: Orange, 50/50, wet; sands very fine to very coarse grained, poorly sorted; gravels bimodal: chert and quartz gravels, mostly granule and small pebble size; large gravel (20 - 50 mm) is very fossiliferous limestone clasts.	3.0 recovery at 36 ft.
39			U/SDGR	Sand and Gravel: As above, numerous shell fragments	Sampler Refusal at 40.0 ft.
40		50	U/MARL	Marl: Limestone, weathered, chalky, fissile.	Drove 1 1/2 in. 5.5 ft. sampler; 50 blows = 1 in.; T.D. = 40.1.

DRILLING LOG	RADIAN CORPORATION	INSTALLATION: CARSWELL AFB, TX	SHEET 1 OF 2 SHEETS
1. PROJECT: CARSWELL AFB, IRP PHASE II STAGE 2		7. TOTAL DEPTH OF HOLE: 37.7 ft BGL	
2. LOCATION: Flightline Area		8. DATUM FOR ELEVATION SHOWN: sea level	
3. DRILLING AGENCY: Environmental Drillers, Inc.		9. MANUFACTURER'S DESIGNATION OF DRILL: Mobile Drill B-61	
4. HOLE NO.: LF04-02		10. NO. OF SAMPLES TAKEN: 14	
5. NAME OF GEOLOGIST: S. E. Fain		11. ELEVATION GROUND WATER: 597.45 ft MSL (6/18/90)	
6. COORDINATES OF HOLE: X: 2020510.50 Y: 397732.54		12. DATE HOLE ESTABLISHED: 3/28/90	
		13. SURFACE ELEVATION: 621.00 ft MSL	
		14. BACKGROUND:	
		15. MEASURING POINT ELEVATION: 623.68 ft MSL	

Depth (Ft.)	Graphic Log	Blow Count	Soil Class/Code	Visual Description	Remarks
0			U/CLLR	Clay: Dark brown, silty, firm, roots, damp, carbonaceous staining.	Full samplers unless noted.
2			U/CLLR	Clay: As above; at 3.0 ft. going to orange/brown, silty clay with 5 - 10% calcareous material.	
4			U/CLLR	Clay: As above.	1.5 ft. Recovery
6			U/CLLR	Clay: Orange/brown, very silty, minor very fine grained sand, stiff, calcareous nodules, carboaceous streaking.	
8			U/CLLR	Clay: As above, increasing calcareous material to 30%.	
11			U/SDGR	Sand and Gravel: Orange, very poorly sorted, cohesive, clayey, silty, damp, abundant calcareous material.	
13			U/SDLR	Sand: Orange, fine grained, minor larger sizes to coarse, slightly clayey and silty, damp.	
13.5			U/SDLR	Sand: As above, increasing coarseness with depth, 5 - 10% small gravels.	
16.5			U/SDLR	Sand: As above, gravelly; changing to tan, fine to medium grained, loose, quartzose at 18.0 ft., damp.	
18.5			U/SDLR	Sand: As above, well sorted, medium grained, damp; 0.4 ft gravelly zone at 21.5 - 21.9 ft.	3.5 ft. Recovery

DRILLING LOG	RADIAN CORPORATION	INSTALLATION: CARSWELL AFB, TX	SHEET 2 OF 2 SHEETS
1. PROJECT: CARSWELL AFB, IRP PHASE II STAGE 2		7. TOTAL DEPTH OF HOLE: 37.7 ft BGL	
2. LOCATION: Flightline Area		8. DATUM FOR ELEVATION SHOWN: sea level	
3. DRILLING AGENCY: Environmental Drillers, Inc.		9. MANUFACTURER'S DESIGNATION OF DRILL: Mobile Drill B-61	
4. HOLE NO.: LF04-02		10. NO. OF SAMPLES TAKEN: 14	
5. NAME OF GEOLOGIST: S. E. Fain		11. ELEVATION GROUND WATER: 597.45 ft MSL (6/18/90)	
6. COORDINATES OF HOLE: X: 2020510.50 Y: 397732.54		12. DATE HOLE ESTABLISHED: 3/28/90	
		13. SURFACE ELEVATION: 621.00 ft MSL	
		14. BACKGROUND:	
		15. MEASURING POINT ELEVATION: 623.68 ft MSL	

Depth (Ft.)	Graphic Log	Blow Count	Soil Class/Code	Visual Description	Remarks
23.5			U/SDLR	Sand: Orange/tan, medium grained, well sorted, subround, >90% quartz; 0.3 ft. gravelly zone at 27 ft., saturated at 28 ft.	4.0 ft. Recovery
28.5			U/SDLR	Sand: As above, 1-3% granule size gravel.	W. L. measured at 28.1 ft. BLS, 5.0 ft. Recovery
33.5			U/SDLR	Sand: Tan, medium grained, quartzose, loose, wet, 5% gravels to 25 mm.	3.7 ft. Recovery.
37			U/MARL	Limestone: Marly, weathered sand and gravel intermixed, fissile.	T.D. = 37.7 ft.

DRILLING LOG	RADIAN CORPORATION	INSTALLATION: CARSWELL AFB, TX	SHEET 1 OF 2 SHEETS
1. PROJECT: CARSWELL AFB, IRP PHASE II STAGE 2		7. TOTAL DEPTH OF HOLE: 37.6 ft BGL	
2. LOCATION: Flightline Area		8. DATUM FOR ELEVATION SHOWN: sea level	
3. DRILLING AGENCY: Environmental Drillers, Inc.		9. MANUFACTURER'S DESIGNATION OF DRILL: Mobile Drill B-61	
4. HOLE NO.: LFO4-03		10. NO. OF SAMPLES TAKEN: 14	
5. NAME OF GEOLOGIST: S. B. Blount, S. E. Fain		11. ELEVATION GROUND WATER: 597.58 ft MSL (6/18/90)	
6. COORDINATES OF HOLE: X: 2020506.79 Y: 397683.46		12. DATE HOLE ESTABLISHED: 3/20/90	
		13. SURFACE ELEVATION: 620.50 ft MSL	
		14. BACKGROUND:	
		15. MEASURING POINT ELEVATION: 623.25 ft MSL	

Depth (Ft.)	Graphic Log	Blow Count	Soil Class/Code	Visual Description	Remarks
0			U/CLAY	Clay: Brown, soft to firm, semi-plastic, with fine rootlets and minor carbonaceous streaking and particles, moist to wet.	Full recovery unless otherwise indicated.
2			U/CLAY	Clay: As above, firm to stiff (stiffens to base), minor calcareous debris, more abundant carbonaceous staining, very stiff; 3.8 - 4.0 ft.	Too stiff to cut.
4			U/CLLR	Clay: Orange/brown at 4.1 ft; brittle, damp, abundant calcareous debris, slickensided, calichified with some authigenic mineralization (crystals of CaCO3 in shell frags.); very hard, silty.	Hard pushing.
6			U/CLLR	Clay: As above, very stiff, slightly sandy and silty.	
8			U/CLLR	Clay: As above, few large CaCO3 pebbles (25 mm), increasing calcareous material with depth, very fine grained sand.	1 ft. recovery, ST. Rig broken. Continue after repairs.
10			U/CLLR	Clay: Orange/brown, silty, cohesive, damp, > 30% calcareous material, stiff.	Caliche layer at 12 ft., drilling through.
12.1			U/SDFN	Sand: Orange, fine grained, loose, damp, quartzose, well sorted; at 14.3 ft. sharp change to tan, very fine grained sand, heavily oxidized in laminae.	
14.5			U/SAND	Sand: Orange, fine to medium grained, quartzose, damp, loose; gravelly seam 15 - 15.5 ft.	3 ft. Recovery.
19.5			U/SDLR	Sand: Orange/tan, fine to medium grained, damp, loose, subground, > 90% quartz, 1 - 3% small gravel and shells.	4 ft. Recovery.

DRILLING LOG	RADIAN CORPORATION	INSTALLATION: CARSWELL AFB, TX	SHEET 2 OF 2 SHEETS
1. PROJECT: CARSWELL AFB, IRP PHASE II STAGE 2		7. TOTAL DEPTH OF HOLE: 37.6 ft BGL	
2. LOCATION: Flightline Area		8. DATUM FOR ELEVATION SHOWN: sea level	
3. DRILLING AGENCY: Environmental Drillers, Inc.		9. MANUFACTURER'S DESIGNATION OF DRILL: Mobile Drill B-61

5. NAME OF GEOLOGIST: S. B. Blount, S. E. Fain		11. ELEVATION GROUND WATER: 597.58 ft MSL (6/18/90)	
6. COORDINATES OF HOLE: X: 2020506.79 Y: 397683.46		12. DATE HOLE ESTABLISHED: 3/20/90	
		13. SURFACE ELEVATION: 620.50 ft MSL	
		14. BACKGROUND:	
		15. MEASURING POINT ELEVATION: 623.25 ft MSL	

Depth (Ft.)	Graphic Log	Blow Count	Soil Class/Code	Visual Description	Remarks
24.5			U/SDLR	Sand: Orange/tan, fine to medium grained, wet, loose, 0.5 ft. gravelly zone at 27 ft., quartzose; at 30 ft.	W. L. measured at 26.3 ft. Bls. 2.6 ft. recovery.
29.5			U/SDLR	Sand: As above, saturated.	3.2 ft. Recovery.
32			U/GRVL	Gravel: Varicolored, up to pebble size (30 mm), shells, <10% sand, saturated.	
34.5			U/GRVL	Gravel: As above, mainly small pebble size (5 - 10 mm), shells, subangular to subrounded, large percentage of chert.	
37.5		50	U/MARL	Marl: Chalky gray, indurated, oxidation stained throughout.	Sampler refusal at 37.5 ft., drove 1 1/2 in. S.S. 50 blows = 1 in.; T.D. = 37.6 ft.

DRILLING LOG	RADIAN CORPORATION	INSTALLATION: CARSWELL AFB, TX	SHEET 1 OF 2 SHEETS
1. PROJECT: CARSWELL AFB, IRP PHASE II STAGE 2		7. TOTAL DEPTH OF HOLE: 25.4 ft BGL	
2. LOCATION: Flightline Area		8. DATUM FOR ELEVATION SHOWN: sea level	
3. DRILLING AGENCY: Environmental Drillers, Inc.		9. MANUFACTURER'S DESIGNATION OF DRILL: Mobile Drill B-61	
4. HOLE NO.: LFO4-04		10. NO. OF SAMPLES TAKEN: 10	
5. NAME OF GEOLOGIST: S. E. Fain		11. ELEVATION GROUND WATER: 595.32 ft MSL (6/18/90)	
6. COORDINATES OF HOLE: X: 2021365.82 Y: 397554.53		12. DATE HOLE ESTABLISHED: 3/20/90	
		13. SURFACE ELEVATION: 609.40 ft MSL	
		14. BACKGROUND:	
		15. MEASURING POINT ELEVATION: 612.07 ft MSL	

Depth (Ft.)	Graphic Log	Blow Count	Soil Class/Code	Visual Description	Remarks
0			U/CLLR	Clay: Red/brown, sandy, silty, damp, cohesive, roots; increasing sand with depth.	Full sample recoveries unless noted.
1.5			U/SDSM	Sand: Red/brown, clayey, cohesive, minor small gravel, damp, decreasing clay content with depth.	1.6 ft. Recovery.
4			U/SAND	Sand: Orange, fine to medium grained, slightly cohesive, quartzose, damp, subangular to subrounded.	
6			U/SAND	Sand: As above, only tan and loose.	1.7 ft. Recovery.
8			U/SAND	Sand: As above, damp.	1.5 ft. Recovery.
10			U/SDLR	Sand: Tan with occasional iron stained thin beds, loose, damp, fine to medium grained; 1 - 3% gravels starting at 12.5 ft.	3.7 ft. Recovery.
13.7			U/SDGR	Sand and Gravel: Fine sand to pebble size gravel, slightly clayey, shells, 50/50 sand to gravel, mainly quartz/chert, wet.	3.5 ft. Recovery.
19			U/GRSM	Gravel and Sand: As above, but gravel content increasing to 70%, gravels mostly 5 - 10 mm; but some to 40 mm, sand mainly coarse grained, limestone clasts; 23 - 24 ft. slightly indurated - increased limestone content.	4.0 ft. Recovery.

DRILLING LOG	RADIAN CORPORATION	INSTALLATION: CARSWELL AFB, TX	SHEET 2 OF 2 SHEETS
1. PROJECT: CARSWELL AFB, IRP PHASE II STAGE 2		7. TOTAL DEPTH OF HOLE: 25.4 ft BGL	
2. LOCATION: Flightline Area		8. DATUM FOR ELEVATION SHOWN: sea level	
3. DRILLING AGENCY: Environmental Drillers, Inc.		9. MANUFACTURER'S DESIGNATION OF DRILL: Mobile Drill B-61	
4. HOLE NO.: LF04-04		10. NO. OF SAMPLES TAKEN: 10	
5. NAME OF GEOLOGIST: S. E. Fain		11. ELEVATION GROUND WATER: 595.32 ft MSL (6/18/90)	
6. COORDINATES OF HOLE: X: 2021365.82 Y: 397554.53		12. DATE HOLE ESTABLISHED: 3/20/90	
		13. SURFACE ELEVATION: 609.40 ft MSL	
		14. BACKGROUND:	
		15. MEASURING POINT ELEVATION: 612.07 ft MSL	

Depth (Ft.)	Graphic Log	Blow Count	Soil Class/Code	Visual Description	Remarks
24			U/GRSM	Gravel and Sand: As above.	
25		50	U/MARL	Limestone: (Marl) White/gray with iron staining in fractures, indurated, shaley parting.	Sampler refusal at 25.0 ft., well drive 5.5 ft.; 50 blows = 4.0 in.; T.D. = 25.4 ft.

DRILLING LOG	RADIAN CORPORATION	INSTALLATION: CARSWELL AFB, TX	SHEET 1 OF 2 SHEETS
1. PROJECT: CARSWELL AFB, IRP PHASE II STAGE 2		7. TOTAL DEPTH OF HOLE: 26.1 ft BGL	
2. LOCATION: Flightline Area		8. DATUM FOR ELEVATION SHOWN: sea level	
3. DRILLING AGENCY: Environmental Drillers, Inc.		9. MANUFACTURER'S DESIGNATION OF DRILL: Mobile Drill B-61	
4. HOLE NO.: LFO4-05		10. NO. OF SAMPLES TAKEN: 12	
5. NAME OF GEOLOGIST: S. B. Blount		11. ELEVATION GROUND WATER:	
6. COORDINATES OF HOLE: X: 2020805.42 Y: 397347.91		12. DATE HOLE ESTABLISHED: 3/28/90	
		13. SURFACE ELEVATION: 608.80 ft MSL	
		14. BACKGROUND:	
		15. MEASURING POINT ELEVATION:	

Depth (Ft.)	Graphic Log	Blow Count	Soil Class/Code	Visual Description	Remarks
0			U/CLLR	Clay: Dark brown grading to brown and orange mottled, fine roots, soft to firm, damp, silty with minor (< 5%) calcareous debris and carbonaceous streaking.	Full samplers unless noted otherwise.
2			U/CLLR	Clay: As above, calcareous debris in small caliche pockets (<5 mm).	1 ft. Recovery.
4			U/CLLR	Clay: As above, calcareous debris zone 4.6 - 4.9 ft., otherwise less than 5%; softer, moist.	1 ft. Recovery.
6			U/CLLR	Clay: As above, mottling decreased - uniform orange color; calcareous debris and rootlets < 2%; increased silt to almost clayey silt.	1.5 ft. Recovery.
8.8			U/SDSM	Sand: Tan/buff at 8.8 ft.; very fine to fine grained, moderate to poor sorting, subangular, quartzose with > 95% quartz and heavy minerals, very loose, damp, minor clay lenses at top, few coarse shell fragments.	1.5 ft. Recovery, Very sharp contact, sample disturbed (in pile).
11.1			U/SDGR	Sand and Gravel: at 11.1 ft. sand is as above, oxidized orange, wet, very poorly sorted; gravel is ~ 30%, average 10 mm, CaCO3, minor clay makes entire sample fairly cohesive; Clay increases to 13 ft.	1 ft. Recovery.
12			U/GRSM	Gravel, Sand, and Clay: As above, gravel up 40%.	Water in hole at 12 ft.; W. L. = 12.72 ft., 13 to 14 ft. no recovery.
14			U/GRSM	Gravel and Sand: As above, with minor clay.	
16			U/GRSM	Gravel and Sand: Orange, 60% + gravel, average 20 mm up to 80 mm; very poor sorting, subrounded; coarse fraction predominantly CaCO3 frags; finer fraction predominantly varicored subrounded quartz grains; some small shell frags (sand sized), very loose; wet.	Poor recovery; gravel slipped out.
19			U/GRSM	Gravel and Sand: As above, gravel is 'coarse' as above - average 20 mm; sand is fine to coarse grained, quartzose, loose, wet, very poorly sorted, subangular.	Possibly gravel only; sample poor; sand recovered may be sluff.

Depth (Ft.)	Graphic Log	Blow Count	Soil Class/Code	Visual Description	Remarks
44.1			U/CLLR	Clay: 44.1 ft. clay is soft, very plastic, moist to wet, grey tan in color with abundant oxidation pockets (< 5 mm) around fine grained sand. Abundant carbonaceous flecks; silty below 46.5 ft. with silt layer 46.5 - 46.7 ft.	4.0 ft. Recovery. Sharp contact. Clay not 'sandy'; has few grains in each 'pocket'.
49			U/MARL	Marl: Clayey coated micritic limestone w/ recrystallized fossils, grey to buff, well indurated, 'mudstone'.	49 - 49.1 ft. augered into marl; 'core' sample. No SS. T.D. at 49.1 ft.

Depth (Ft.)	Graphic Log	Blow Count	Soil Class/Code	Visual Description	Remarks
0			U/CLLR	Clay: Soft - firm, moist, clay fraction plastic - semi - brittle due to roots, calcareous pebbles, slightly silty with clayey silt 1.7 - 2 ft., yellow orange grading to brown.	Full recovery unless otherwise indicated. Extremely windy.
2			U/CLLR	Clay: As above, calcareous pebbles concentrated in intervals, less silty, minor carbonaceous streaking at base.	Gradational changes.
4			U/CLAY	Clay: As above, Brown, firm, fairly plastic, layers of concentrated calcareous debris.	
6			U/CLLR	Clay: As above, dark brown, grading darker, soft to firm, very few calcareous pebbles, abundant carbonaceous lamina, very few fine rootlets, moist, minor silt in lenses, plastic - appears organic rich.	
10			U/CLLR	Clay: As above, dark brown, soft, plastic, moist with silty/sandy lenses to 13.2 ft.; leached zones 13.2 - 13.5 ft., 14.3 - 14.4 ft., clay is white/buff, brittle, damp, with more frequent calcareous pebbles, intervening clay is as above; with silt/sand.	Musky odor. Caliche zones. 1.5 ft. recovery.
14.4			U/CLLR	Clay: As above soft/firm with abundant carbonaceous lamina, fine roots, dark brown, minor leached pebble zone 14.8 ft.	
15.2			U/SDSM	Sand: Buff. Moist to wet, very fine grained, silty, poor - moderate sorting.	Water in hole - 15 - 16 ft.. Sharp contract.
16			U/CLLR	Clay: As above, dark brown, carbonaceous stains, soft to firm, moist, calcareous pebbles, minor oxidation stains.	
16.5			U/SDLR	Sand: As above, silty, color lamina (oxidation layers), fine roots, gravel - 17.6 - 18 ft.; buff; sand is quartzose with > 95% quartz, minor cohesive clay lenses, otherwise loose, minor carbonaceous streaking; clay lenses and intermittent pebbles decrease to 20 ft.	Few pebbles.
20			U/SDGR	Sand: As above, buff yellow, and gravel to 22 ft., sand	Not likely fill

0			U/CLAY	Clay: Brown, soft, damp, brittle, root bound with fine rootlets, minor other plant debris.		
2			U/CLAY	Clay: Medium brown, firm, plastic, moist, minor rootlets, few calcareous flecks at base.		
4			U/CLAY	Clay: Grey/grey, mottled, very stiff, dry to damp, very minor fine rootlets, abundant calcareous debris.	Could not cut w/ carpet knife.	
8			U/CLLR	Clay: As above, calcareous pebbles up to 15 mm; stiff. Predominately debris 1 - 2 mm.	Pebbles effervesce in HCl solution.	
10			U/CLLR	Clay: As above, firm, plastic.		
11			U/CLLR	Clay, Sand, and Gravel: Very poorly sorted, rounded gravel, moist. Clay dominates to 12 ft. with small soil developed on top, buff/yellow. Sand content increases to base.	Musky odor. Terrace dep.? (Soil).	
12				U/SAND	Sand: Buff/yellow, very fine to fine grained, slightly clayey/cohesive at top, loose below 12.3 ft., moderate rounding, well sorted, > 95% quartz.	Water in hole at 12 ft.; go to 5 ft. samplers.
14.5				U/LMSN	Limestone: Grey to light grey, marly, fissile, weathered. 10 mm indurated layers with thin marls between, no shells, micritic appearance.	Drilled slowly into limestone. Refusal at 14.5 ft. 0.5 ft. Recovery. Driller says layered marl, drive SS; 1 ft. Recovery.
17.5			50	U/LMSN	Limestone: Well indurated, calcareous shale - fissile, medium grey, slightly 'carbonaceous'; contiguous 'bed' from 17.5 - 18.3 ft.	T.D. at 18.3 ft.. Water level = 12.67 ft. (BGL).

		15. MEASURING POINT ELEVATION:	

Depth (Ft.)	Graphic Log	Blow Count	Soil Class/Code	Visual Description	Remarks
0			U/CLLR	Clay: Medium dark brown with minor carbonaceous streaking, firm, plastic, moist. Calcareous pebbles abundant to 0.4 ft., minor roots, few pebbles to 3 ft.	Full recovery unless otherwise noted.
3.2			U/CLLR	Clay: Very stiff, dark brown with obvious carbonaceous streaking, minor sandy lenses, damp to moist, brittle, hard, sand lamination at upper contact is parting; fine rootlets and intervals with coarse sand/pebbles to 6 ft.	Can not cut - seems too dense to be fill. 1 ft. Recovery in ST. Crushed heavy gauge sampler.
6			U/CLLR	Clay: Calichified (leached) white to buff, brittle, firm, shell fragments, damp, abundant calcareous debris, abundant orange oxidation seams, visible authigenic mineralization, silty appearance.	Full 2 ft. push with no recovery. SS pushed 6 - 8 and got 0.9 ft. recovery.
7.5			U/CLLR	Clay: Stiff, as above, interlayered with calichified zones to 13.2 ft.; stiff clay has intervals of abundant calcareous debris and grades into caliche then abruptly goes back to clay as 6 - 7 ft.	Pushed SS - 0.8 ft. Recovery; used 5 ft. sampler from 12 - 14.5 ft.; 0.3 ft. recovery.
13.2			U/CLLR	Clay: Medium brown/yellow, moist to wet, brittle, silty, abundant calcareous debris.	
14.5			U/MARL	Marl: Weathered limestone marl at 14.5 ft.; clay rich, soft, oxidized in seams, abundant broken micritic limestone fragments, wet (saturated - soggy), semi-plastic, buff/yellow.	Water in hole 14.5 - 19.5 ft.. 3.5 ft. recovery.
16			U/CLLR	Clay and Gravel: Gravel < 20%, clay is buff, firm to stiff, moist, oxidation seams, chalky, CaCO ₃ , rich, with coarse fragments, silty, semi-fissile.	
18			U/MARL	Marl: Dark grey, semi-indurated, highly calcareous, shaley, fissile, dense, dry to damp.	
19.5			U/GRSM	Gravel, Sand, and Clay: Gravel up to 80%, orange/yellow, brittle/friable, soft, wet to moist. Sand very poorly sorted, very fine to coarse grained, subangular, wet, gravel up to 40 mm, quartz and CaCO ₃ and minor shell fragments, slightly cohesive.	4.2 ft. Recovery.

5. NAME OF GEOLOGIST: S. B. Blount		11. ELEVATION GROUND WATER:	
6. COORDINATES OF HOLE: X: 2021241.43 Y: 398317.23		12. DATE HOLE ESTABLISHED: 3/19/90	
		13. SURFACE ELEVATION: 606.50 ft MSL	
		14. BACKGROUND:	
		15. MEASURING POINT ELEVATION:	

Depth (Ft.)	Graphic Log	Blow Count	Soil Class/Code	Visual Description	Remarks
0			U/CLLR	Clay: Brown, soft - firm, silty with minor very fine grained sand, roots, moist, minor calcareous pebbles and carbonaceous staining, semi-plastic.	Full recovery unless otherwise noted.
3			U/CLLR	Clay: As above at 3 ft., with abundant calcareous pebbles.	
3.2			U/GRCL	Gravel, Clay, and Sand: Gravel is calcareous, dry to damp, calichified, < 15 mm, buff, wetness increases with depth, very poorly sorted with clay lenses. Clay is as above.	Gravel Contacts.
4.5			U/SAND	Sand: Sand is very fine grained - fine grained, orange oxidized at top grading to buff/yellow at 5 ft., subrounded, moderately well sorted, moist, quartzose with > 95% quartz, small shell fragments abundant to 10 ft. Grain size up to sand/gravel at 6.8 ft., then very fine grained	Sharp Contact.
9.4			U/CLLR	Clay: Minor shell fragments.	
10			U/SDVF	Sand: As above, very fine grained, well sorted, subangular to subround, moist to wet, color laminated, > 95% quartz.	2.5 ft. Recovery.
14			U/SDVF	Sand: As above.	No visible contamination, but high Drager readings 1 ft. Recovery.
16			U/SDVF	Sand: As above.	No odor.
16.5	 50		U/MARL	Marl/Limestone: Micritic, light grey, dense, many small fossils (recrystallized), well indurated, chalky surface.	Sample description from small fragments, apparently very hard. T.D. at 16.6 ft.

Depth (Ft.)	Graphic Log	Blow Count	Soil Class/Code	Visual Description	Remarks
0			U/CLLR	Clay: Orange/brown, silty, stiff, damp, roots; calcareous nodules starting at 2 ft.	Full recoveries unless noted otherwise.
2			U/CLLR	Clay: As above.	1.6 ft. Recovery.
4			U/CLLR	Clay: Orange/brown, abundant calcareous nodules and streaking, limestone gravels, damp.	
6			U/CLLR	Clay: As above, iron oxidation, carbonaceous streaking, less calcareous material.	
8			U/CLLR	Clay: Becoming siltier, damp, brick fragments.	Fill material.
10.8			U/CLLR	Clay: As above, 2 in. limestone zone.	
11			U/SAND	Sand: Orange, fine to medium grained, loose, damp, bedding evident in slight color changes.	3 ft. Recovery.
16			U/SAND	Sand: Orange/tan, fine to medium grained, loose, damp, > 90% quartz; going to predominately medium to coarse grained 18 - 20 ft., wet at - 19 ft. BLS.	3.5 ft. Recovery..
20			U/SAND	Sand: As above, saturated, subrounded.	Measured W.L. is 19.35 ft. BLS; W.L. measured at 18.65 ft. BLS after well

Depth (Ft.)	Graphic Log	Blow Count	Soil Class/Code	Visual Description	Remarks
0			U/CLAY	Clay: Dark brown first 1 ft., then orange/brown with abundant calcareous material, damp, cohesive.	0.3 ft. Recovery. Stuck in shelby tube.
2			U/SDMD	Sand: Orange, cemented 3 - 4 ft., medium grained, dry.	
4			U/SAND	Sand: Orange, fine to medium grained, quartzose, damp, loose.	1 ft. Recovery.
6			U/LMSN	Limestone: 1 in. limestone bed underlain by 2 in. cemented sand at 6.0 ft.	
6.3			U/SDGR	Sand and Gravel: Orange, poorly sorted, very fine grained sand to pebble size gravel, damp. Gravel is subround.	1 ft. Recovery.
10			U/SDGR	Sand and Gravel: Orange, 60% sand, 40% gravel, damp, oxidation staining 11 - 13 ft; occasional limestone cobbles and thin beds, saturated at ~ 13.5 ft.	4.2 ft. Recovery.
13.7			U/GRSM	Gravel and Sand: As above but > 80% gravels (mainly 2 - 10 mm), saturated, assorted sand sizes, gravels mainly subround chert and angular limestone clasts.	W.L. measured at 13.6 ft. 3.6 ft. Recovery.
19			U/GRSM	Gravel and Sand: 80% gravels 2 to 25 mm, 20% assorted sand sizes, saturated, numerous shells (gryphea?); 19 - 19.3 ft. medium sand bed.

1.0 INTRODUCTION

The IRP Phase I and Phase II investigations have identified the Flightline Area at Carswell AFB as an on-base site where past waste disposal practices may have led to contamination of soils and ground water. These studies have identified a need to understand the hydrogeologic framework controlling the occurrence of ground water and the factors influencing the direction and rate of ground-water flow. Therefore, an aquifer pumping and recovery test was conducted at the Flightline Area during June, 1990 as part of an on-going IRP Remedial Investigation/Feasibility Study (RI/FS). The objective of the aquifer tests was to determine the hydraulic characteristics of the shallow ground-water bearing zone (Upper Zone Aquifer). The following sections describe the geologic setting of the Flightline Area, aquifer test procedures, and test results.

1.1 Principles of Aquifer Pumping Tests

The value of an aquifer as a source of ground water depends upon water quality and the capacity of the aquifer to store and transmit water. The latter two characteristics are referred to as the properties of storage and transmissivity. The transmissivity is a function of an aquifer's hydraulic conductivity. The hydraulic conductivity is defined as the flow of water in cubic feet per day through a cross-sectional area of one square foot under a hydraulic gradient of one foot per foot (Davis and DeWeist, 1966).

Transmissivity is a measure of the volume of water which will flow each day through a one foot wide vertical strip of aquifer which extends the full saturated height of the aquifer. The transmissivity is equal to the product of the hydraulic conductivity and the saturated thickness of the aquifer, and indicates the capacity of the aquifer as a whole to transmit water (Theis, 1935).

The storage coefficient is a dimensionless term defined as the volume of water the aquifer releases from or takes into storage per unit surface area of the aquifer per unit change in the component of head normal to

that surface (Walton, 1962). The storage coefficients of unconfined aquifers (e.g., water table aquifers), such as the Upper Zone Aquifer in the Flightline Area, usually range from 0.005 to 0.30 (Ferris, et al., 1962). Unconfined aquifers usually have higher values for storage coefficients than confined aquifers, and these higher values reflect that releases from storage represent mostly pore dewatering, whereas in confined aquifers, releases from storage represent the effects of water expansion and aquifer compaction due to changes in fluid pressure (Freeze and Cherry, 1979). The storage term for unconfined aquifers is also known as the specific yield.

Storage and transmissivity are commonly determined by conducting aquifer tests in wells completed in water-bearing units. Aquifer testing may include constant discharge pump tests, variable rate (step) discharge tests, constant drawdown tests, water level recovery tests, and slug tests.

At the Flightline Area, a constant discharge pump test and water-level recovery tests were conducted to determine the hydraulic properties of the geologic units which contain contaminated ground water. In a constant discharge pump test, a well is pumped at a constant rate and water levels are measured for the duration of the test in the pumping well and in the observation wells which penetrate the water-bearing unit. During the recovery test, the change in the water levels in the wells are recorded after cessation of pumping until near static water levels are attained. Graphs of drawdown and recovery versus time after pumping started and stopped are compared to graphs calculated from mathematical aquifer models to estimate the aquifer parameters.

2.0 GEOLOGIC SETTING

The geologic setting of the Flightline Area at Carswell AFB is described in detail in the main body of this report. Specifically, Section 3.3 provides information about the geologic setting, topography, and stratigraphy. Section 3.4 contains a detailed description of the hydrogeology for the Flightline Area. The reader is referred to these sections prior to proceeding with the remainder of this appendix.

The following paragraphs are provided to supply additional information about the subsurface conditions in the area immediately affected by the aquifer tests.

Soil boring data collected during well installation in the vicinity of the aquifer test location has revealed a coarsening downward sequence of lithologies from land surface to bedrock, which is comprised of the Goodland and Walnut Formations.

The deposits from the surface to bedrock (referred to as "Upper Zone" deposits) are generally 30 to 40 feet thick and consist of 10 to 15 feet of fine grained materials (clay and silt) underlain by 20 to 30 feet of sands and gravels. The thickest sequence of coarser grained materials (sands and gravels) is generally oriented in an east to west trend through the Flightline Area, roughly paralleling White Settlement Road. These deposits are unconsolidated and coarsen downward to predominantly limestone and chert gravels at the contact with the underlying bedrock.

Bedrock of the Goodland and Walnut Formations consists of interbedded, fossiliferous, hard limestone and calcareous shale. The thickness of the Goodland and Walnut Formations in the vicinity of the pumping test location is approximately 30-40 feet. The Goodland and Walnut Formations have been dry when sampled during drilling activities in the area, and with the thickness and hardness of the formations they are believed to form an effective confining layer between the Upper Zone water-bearing deposits and the underlying water-bearing sands of the Paluxy Formation.

The water-bearing zone (Upper Zone Aquifer) immediately adjacent to the pumping well (LFO4-03) is an unconfined, or water-table, aquifer. The water table as encountered in the subsurface is under atmospheric pressure, and wells completed in the aquifer will reflect the actual water level. This is in opposition to confined aquifers where wells tapping the aquifer may have water levels considerably above the top of the aquifer.

Water levels from wells LFO4-02 and LFO4-03 were electronically monitored during the pump test and recovery test. The lithologic logs of these wells and well construction data are located in Attachment A.

Well LFO4-03, the pumping well, is screened across the lower 14.3 feet of Upper Zone sediments. These sediments are mainly medium grained sand with minor gravels in the upper 10 feet of screened interval, and the lower section of the screen is across predominantly small pebble size gravels (< 10% sand).

Well LFO4-02, 50 feet north of the pumping well and the nearest observation well, is screened across similar units as LFO4-03. This well also has 14.3 of screen. Again, the screened interval encompasses medium sands, however, the gravel content is not as high near the bottom of the screened interval (approximately 5% gravels) as in LFO4-03.

The water table, prior to the start of the aquifer test, occurred approximately 25 feet below land surface in the vicinity of the pump test location. The saturated thickness of the Upper Zone Aquifer was calculated to be 11.7 at the pump well (LFO4-03).

In addition to the pump well and near observation well, seven other monitor wells in the vicinity of the pump test location were used as observation wells. These wells are all screened across Upper Zone Aquifer sediments, and vary in distances of 100 to 450 from the pump well (Figure 2-1).

Figure 2-1. Location of Pumping Well and Observation Wells, Flightline Area Pump Test, Carswell AFB, Texas

3.0 FIELD INVESTIGATION

3.1 Pumping Test Procedures

The Flightline Area aquifer pump test was conducted June 21-22, 1990 and ran for 20 hours. The recovery test, which started with the cessation of the pump test, ran for 7 2/3 hours.

3.1.1 Discharge Water

Discharge water produced during the pump test was run through over 300 feet of polyethylene pipe before being routed into the City of Fort Worth sewer system. Pumping rates were measured approximately every hour using a bucket and stopwatch (volumetrically). The temperature, pH, and conductivity of the discharge water was also measured regularly. The discharge of the pump remained constant through the test, with measured discharges (17) varying from 17.9 to 18.7 gallons-per-minute (gpm). The averaged discharge was 18.3 gpm, leading to an approximate total discharge of 22,000 gallons during the pump test.

At the request of the City of Fort Worth Water Department, the discharge water was aerated for removal of volatile organic compounds (VOCs).

Aeration of the pump test discharge water, prior to sanitary sewer discharge, was accomplished with a trailer mounted 125 cfm air compressor. Air from the compressor was routed to a small holding pond which was receiving water from the pumping well. A hole in the top of the holding pond (swimming pool) allowed for discharge of the aerated water to the sewer system.

Periodically during the pump test, water samples going into the holding pond (pre-aeration) and exiting the pond (post-aeration) were collected. These samples were collected in 40 ml VOA vials, filling each approximately 2/3's with water. These water samples were then allowed to sit in the open sun for several hours prior to a headspace analysis for volatile

organic content. The time spent in the sun allowed volatile organics in the ground-water samples to volatilize to the overlying air column. The volatile organic content of the air (headspace) was then measured with an HNu photo-ionization detector (PID). This was accomplished by cutting a small slit in the Teflon™ septum in the cap of the vial and quickly inserting the probe of the HNu PID. Table 3-1 summarizes the results of the headspace analyses performed on the discharge water samples from the Flightline Area pump test.

As seen from the table, the aeration of the pump test water prior to discharging to the city sewer system reduced the volatile organic content of the water in every sample analyzed. The average reduction, considering all the analyses, was slightly over 40 percent. The HNu PID is not compound specific, instead measuring the total volatile organic content in the air. The instrument was responding very well, and duplicate (D) analyses performed on the samples from 1630 showed only a three percent relative difference.

3.1.2 Test Types and Measurements

Background water-level data in the pumping well and the near observation well were collected electronically (at 10-minute intervals) for approximately 40 hours with a Hermit electronic data logger prior to the step test. The background data are useful for observing natural trends in the Upper Zone Aquifer water level, such as increases from recharge or decreases due to evapotranspiration. A slight downward trend in water levels, followed by a slight recovery, was observed in wells LFO4-02 and LFO4-03. The background water level data for the two wells, as well as hydrographs showing the natural water level trends, are included in Attachment B.

A step test was performed prior to the start of the pumping test to establish the optimum pumping rate. The optimum pumping rate for the Flightline Area pumping test set-up was determined to be the full capacity of the submersible pump (Gould 1/2 HP, Model 10 EJ), or approximately 20 gallons per minute. The pump was rated at approximately 25 gpm (with the amount of

TABLE 3-1. HEADSPACE ANALYSIS

Time Sample Taken	HNu Value (ppm)		Time Sample Analyzed	Background HNu Reading
	Water Going Into Pool	Water Going Into Sewer

1915	12.0	6.8	2120	0.0

(D) - Denotes duplicate sample

hydraulic head encountered in the pumping well); however, travel of discharge water through over 300 feet of polyethylene pipe before ultimate discharge to the sewer system reduced discharge rates proportionately.

The pump test followed the end of the step test by about 16 hours, and measured water levels had recovered to over 99 percent of their pre-step test level. The 4-inch submersible pump (used in pump and step test) was powered by a 3500 watt portable generator.

During both the pumping and recovery tests, water levels in the pumping well (LF04-03) and the near observation well (LF04-02) were recorded using pressure transducers and an automatic data logger (Hermit Model 1000B). The Hermit collected water-level data for the two wells, for both the pump and recovery test, is included in Attachment C. Water levels were also manually measured in surrounding monitor wells with a calibrated Olympic electric water-level probe. The water-level probe was decontaminated prior to each water-level measurement. The water levels in the pumping well and near observation well were also checked regularly with the Olympic meter to verify the accuracy of the Hermit data logger. The manual water-level measurements are provided in Attachment D. The maximum water-level decline observed in the manually measured observation wells was 0.09 feet (LF04-4E). Hydrographs of the water levels in the observation wells during the pump test are also provided in Attachment D.

As seen from the hydrographs, there appears to be a slight water-level rise around 700 minutes into the pump test. The timing of the water-level rise corresponds with a decrease in barometric pressure. Figure 3-1 shows the barometric pressure plotted with the water levels measured in well LF04-4H. This pressure phenomenon appears to have had a slight effect on the water level of the Upper Zone Aquifer, but the barometric pressure goes back up to roughly the same value as when pumping started by the end of the pump test. The overall trend of water levels does not appear to have been affected significantly by the pressure fluctuations. Unconfined aquifers are naturally less affected by barometric pressure fluctuations than confined aquifers.

Figure 3-1. Barometric Pressure Effects on Water Level in Monitor Well LFO4-4H

4.0 TEST RESULTS

4.1 Analytical Methods and Assumptions

The data obtained during the June 1990 Upper Zone aquifer pumping test were analyzed by several methods. In addition to field plotting of drawdown and distance drawdown measurements, a computer aquifer analysis program was used. The well hydraulics interpretation program used was WHIP™, which has the ability to simulate and analyze both drawdown and recovery tests.

Attempts were initially made to interpret the pump test data using the techniques of Boulton (1963) and Newman (1975) for unconfined aquifers. These techniques consider the effects of gravity drainage in an unconfined aquifer, which result in a delayed yield of ground water to the well and a corresponding fluctuation in the time-drawdown data curve. As can be seen from Figure 4-1, delayed yield was not pronounced (if evident) in the loglog plot of the near observation well drawdown. Attempts at matching respective portions of the drawdown curve with various Type A and Type B curves met with no success. Therefore, in the analysis of unconfined aquifer data showing no apparent delayed yield, the techniques of Theis and Jacob-Cooper were applied to the data.

The Theis and Jacob-Cooper analyses were used as both field methods and in later data analysis for estimating aquifer parameters. Time versus drawdown for observation wells were plotted on semi-log paper. From this plot, the change in drawdown over a particular log cycle was used in the calculation of aquifer transmissivity and storativity, using the equations:

$$T = \frac{2.3Q}{4\pi\Delta h} \quad \text{and} \quad S = \frac{2.25Tt_0}{v^2}$$

where: T = transmissivity
 Q = pumping rate
 Δh = the drawdown for one log cycle

Figure 4-1. Loglog Plot of Observation Well (LF04-02) Drawdown

- S = storativity
- t_0 = time intercept where the drawdown line intercepts the zero drawdown axis
- v = radial distance from the pumping well to observation well

The WHIP™ diagnostic procedures also use semilog drawdown (Jacob-Cooper) analyses and Theis recovery analyses to obtain preliminary estimates of the transmissivity and storage coefficient. These curves are generated using these values and are graphically compared to the observed data. Portions of the generated curves can be "windowed" so only reliable data are used for the generation of final transmissivity and storage coefficient values.

In addition to standard semilog and loglog plots, the effects of various time transformations on the data as well as first and second derivatives of the drawdowns were performed. Observing the derivative drawdown plots was useful for determining that portion of the test data displaying Theis behavior. Additionally, the Dupuit correction for water table conditions was applied to all computer analyses and the initial estimates of transmissivities and storage coefficients were optimized using an ordinary least squares fitting criterion. This correction minimizes irregularities inherent in field generated data to improve computer aided curve matching techniques and allow greater accuracy in the calculation of aquifer parameters.

Three different computer generated plots and analyses were determined to best represent the Upper Zone aquifer hydraulic properties of transmissivity and storage coefficient. These were the observation well (LF04-02) drawdown and recovery analyses and the pumping well (LF04-03) recovery analysis.

Seven additional monitor wells were measured for response to the pumping well and there was little if any noted.

4.2 Water Level Behavior in Pumping Well and Near Observation Well

The observed maximum drawdown was 3.58 feet in the pumping well and 0.20 feet in the near observation well, located 50 feet north of the pumping well.

4.3 Results

The results of the computer-assisted pump test analyses are presented in Table 4-1. The drawdown and recovery curves for the observation well were analyzed as well as the recovery curve for the pumping well. The average values for the parameters of transmissivity and hydraulic conductivity and a value for storage coefficient are shown on the table. The averaged values are representative of the types of aquifer materials encountered (clean sands and gravels). The WHIP™ generated plots for the analyses are provided in Attachment E.

TABLE 4-1. SUMMARY OF AQUIFER PUMPING TEST RESULTS, FLIGHTLINE AREA, CARSWELL AFB, TEXAS
(JUNE, 1990)

Well Number	Type of Test Analyses	Distance From Pumping Well (ft)	Transmissivity	Hydraulic Conductivity	Storage Coefficient (Dimensionless)
LF04-02	Drawdown	50	9771 ft ² /day	835 ft/day (2.9 x 10 ⁻¹ cm/sec)	1.2 x 10 ⁻²
	Recovery	50	8260 ft ² /day	705 ft/day (2.5 x 10 ⁻¹ cm/sec)	
LF04-03	Recovery	Pumping Well	9501 ft ² /day	812 ft/day (2.9 x 10 ⁻¹ cm/sec)	
	Average Values		9177 ft ² /day	784 ft/day (2.8 x 10 ⁻¹ cm/sec)	1.2 x 10 ⁻²

4			U/CLLR	Clay: Orange/brown at 4.1 ft; brittle, damp, abundant calcareous debris, slickensided, calichified with some authigenic mineralization (crystals of CaCO3 in shell frags.); very hard, silty.	Hard pushing.
6			U/CLLR	Clay: As above, very stiff, slightly sandy and silty.	
8			U/CLLR	Clay: As above, few large CaCO3 pebbles (25 mm), increasing calcareous material with depth, very fine grained sand.	1 ft. recovery, ST. Rig broken. Continue after repairs.
10			U/CLLR	Clay: Orange/brown, silty, cohesive, damp, > 30% calcareous material, stiff.	Caliche layer at 12 ft., drilling through.
12.1			U/SDFM	Sand: Orange, fine grained, loose, damp, quartzose, well sorted; at 14.3 ft. sharp change to tan, very fine grained sand, heavily oxidized in laminae.	
14.5			U/SAND	Sand: Orange, fine to medium grained, quartzose, damp, loose; gravelly seam 15 - 15.5 ft.	3 ft. Recovery.
19.5			U/SDLR	Sand: Orange/tan, fine to medium grained, damp, loose, subround, > 90% quartz, 1 - 3% small gravel and shells.	4 ft. Recovery.

DRILLING LOG	RADIAN CORPORATION	INSTALLATION: CARSWELL AFB, TX	SHEET 2 OF 2 SHEETS
1. PROJECT: CARSWELL AFB, IRP PHASE II STAGE 2		7. TOTAL DEPTH OF HOLE: 37.6 ft BGL	
2. LOCATION: Flightline Area		8. DATUM FOR ELEVATION SHOWN: sea level	
3. DRILLING AGENCY: Environmental Drillers, Inc.		9. MANUFACTURER'S DESIGNATION OF DRILL: Mobile Drill B-61	
4. HOLE NO.: LFO4-03		10. NO. OF SAMPLES TAKEN: 14	
5. NAME OF GEOLOGIST: S. B. Blount, S. E. Fain		11. ELEVATION GROUND WATER: 597.58 ft MSL (6/18/90)	
6. COORDINATES OF HOLE: X: 2020506.79 Y: 397683.46		12. DATE HOLE ESTABLISHED: 3/20/90	
		13. SURFACE ELEVATION: 620.50 ft MSL	
		14. BACKGROUND:	
		15. MEASURING POINT ELEVATION: 623.25 ft MSL	

Depth (Ft.)	Graphic Log	Blow Count	Soil Class/Code	Visual Description	Remarks
24.5			U/SDLR	Sand: Orange/tan, fine to medium grained, wet, loose, 0.5 ft. gravelly zone at 27 ft., quartzose; at 30 ft.	W. L. measured at 26.3 ft. Bls. 2.6 ft. recovery.
29.5			U/SDLR	Sand: As above, saturated.	3.2 ft. Recovery.
32			U/GRVL	Gravel: Varicolored, up to pebble size (30 mm), shells, <10% sand, saturated.	
34.5			U/GRVL	Gravel: As above, mainly small pebble size (5 - 10 mm), shells, subangular to subrounded, large percentage of chert.	
37.5	 50		U/MARL	Marl: Chalky gray, indurated, oxidation stained throughout.	Sampler refusal at 37.5 ft., drove 1 1/2 in. S.S. 50 blows = 1 in.; T.D. = 37.6 ft.

ATTACHMENT D

Hand Monitored Water-Level Data and Hydrographs of the
Hand-Measured Water-Level Data

AQUIFER TEST DATA

Owner CRAWWELL Address CRAWWELL AFB County _____ State TX

Date 21 June 1990 Measured by Steve Fain, Scott Blount

Well No. LFO4-4E Distance from pumping well _____ Type of test Pumping Test No. _____

Measuring equipment Hand measured with E-line

Time Data		Water Level Data		Discharge Data	
Pump on: Date <u>6-21</u> Time <u>0745</u> (t)	Static water level _____	How Q measured _____			
Pump off: Date <u>6-22</u> Time <u>0547</u> (t)	Measuring point _____	Depth of pump/air line _____			
Duration of aquifer test:	Elevation of measuring point _____	Previous pumping? Yes _____ No _____			
Pumping <u>1202</u> Recovery <u>460</u>		Duration _____ End _____

LFO4-4E

59 317

F-55

59 321

Variables

Saturated thickness = 11.7 ft
 Maximum drawdown (pumping well) = 3.5 ft
 $r = 50$ ft
 $Q = 18.3$ gpm
 Pump well radius = 0.25 ft
 Effective casing radius = 0.7 ft

Results

Transmissivity = 9771 ft²/day
 Storage coefficient = 1.2×10^{-2}
 (Results have Dupuit correction applied and have been optimized with seven iterations by the Levenberg-Marquardt Minimization Algorithm).

Results

Transmissivity = 8260 ft²/day
 (Result has been optimized with seven iterations by the Levenberg-Marquardt Minimization Algorithm).

Windowed data (2,100) on T/TPrime plot used in analysis.

Results

Transmissivity = 9501 ft²/day

(Result has been optimized with seven iterations by the Levenberg-Marquardt Minimization Algorithm).
