Boring 002S0029

Project: NSA Memphis

Location: Millington, TN SHMU#2 - Southside Landfill

Project No.: 106-08420

Geologist: D. Ladd, W. Parks

Started at 0750 on 2-6-96

Surface Elevation: 266.60 feet msl

Completed at 0915 on 2-6-96

Drilling Method: Rotasonic

Total Depth: 55.0 feet

Drilling Company: Alliance Environmental, Inc.

DEPTH IN FEET	LITHOLOGIC SAMPLE	ANALYTICAL SAMPLE	SAMPLE NO.	% RECOVERY	PTD (ppm)	GRAPHIC LOG	SOIL CLASS	GEOLOGIC DESCRIPTION	ELEV. (ft-MSL)
			1	56	BG		OL	(0-35') Upper Alluvium (see descriptions below). (0-3.5') Soil and roots.	
5					BG				263.1
			2	70	BG		ML	(3.5-16') Silt (see descriptions below). (3.5-6') Silt, moderate yellowish-brown mottled with light olive gray, with considerable iron staining. (6-16') Silt, olive gray to light olive gray mottled with moderate yellowish-brown.	
10					BG				
					BG			Moist from 12' to 16'.	
					BG			Contains iron-manganese nodules from 13' to 16'.	
15					BG			Mottled with dark yellowish-orange near 16'.	
			3	100	BG			No description available, collected Shelby tube from 16' to 19' for geotechnical analysis.	250.6
					BG				247.6
20					BG		ML	(19-30') Silt (see descriptions below). (19-26') Silt, olive gray to greenish-gray, with a very few snail fragments, moist. With very fine sand below 22'. Contains roots below 23'. Contains iron-manganese nodules from 24' to 26'.	
			4	100	BG				
					BG			(26-30') Silt, sandy (very fine-grained), olive gray to greenish-gray becoming light olive gray near 30', contains snail shell fragments, moist.	
25					BG			Large piece of wood at 28'.	
					BG			Percentage of sand increases near 30'.	
30							SM		236.6

Project No.: E-3-157

Client's Project No.: 0106090000

Sample I.D.: 002S03DA43

Soil Description: Clean Sand with some small gravel

Test Media: City of Memphis Water

	<u>Pre-Test</u>	<u>Post Test</u>
Wet Density (Lbs/ft ³)	127.6	130.4
Dry Density (Lbs/ft ³)	115.3	115.9
Moisture (% Dry Wt)	10.7	12.5
Porosity (n)	.29	.30
Degree of Saturation (%)	.79	1.0
Specific Gravity (ASTM D-854)	2.68	---

Permeability

Temperature Correction, $R_t = 1.031$

- $K_1 = 8.6 \times 10^{-4}$ cm/sec
- $K_2 = 8.4 \times 10^{-4}$ cm/sec
- $K_3 = 8.7 \times 10^{-4}$ cm/sec
- $K_4 = 8.2 \times 10^{-4}$ cm/sec

Coefficient of Permeability, $K_{20} = 8.6 \times 10^{-4}$ cm/sec

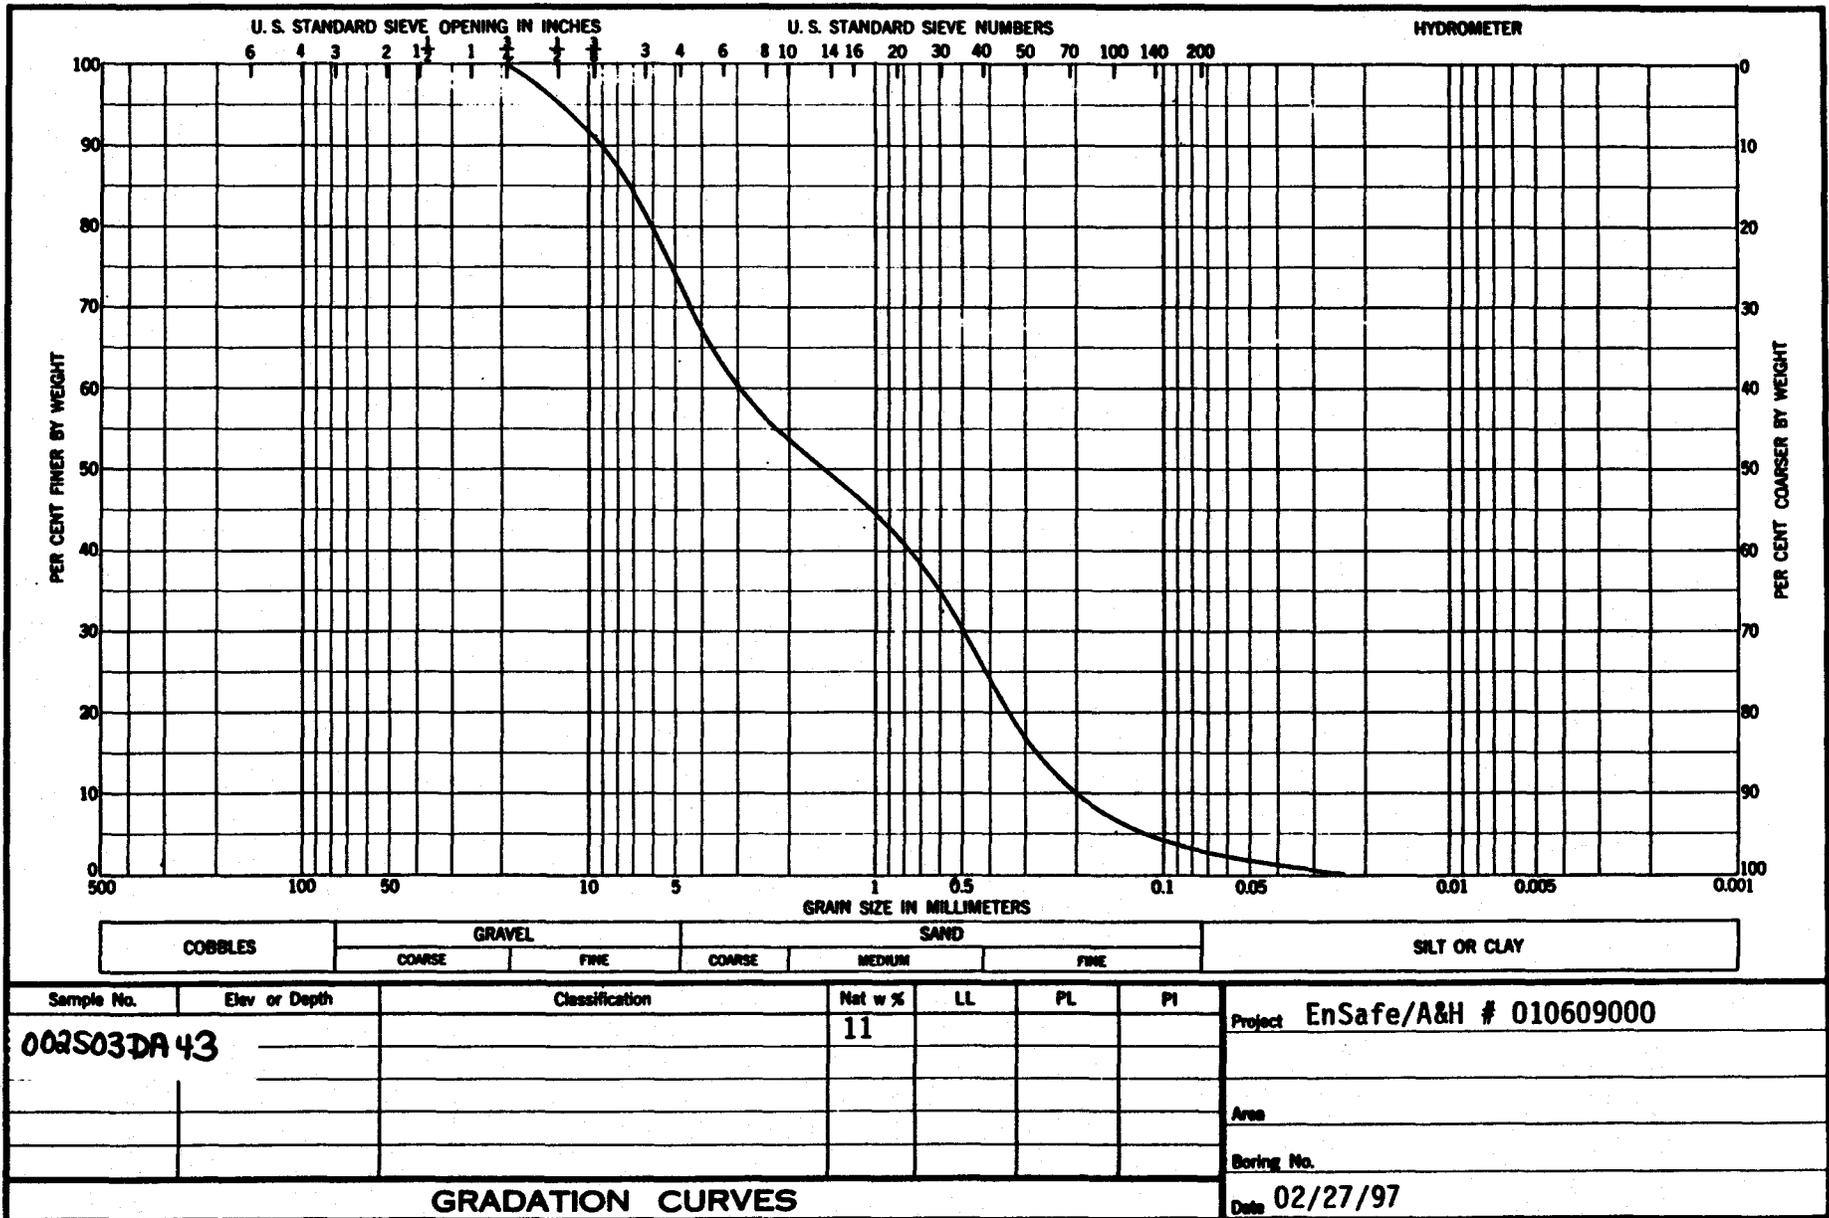

Tested in accordance with ASTM D-5084-90.

Lab No. P-96-009

Measurement of Hydraulic Conductivity

Client: EnSafe/Allen & Hoshall

Date of Report: 03/01/96

Project No.: E-3-157

Client's Project No.: 010609000

Sample I.D.: 065S06DA16

Soil Description: Gray & Brown Clayey Silt

Test Media: City of Memphis Water

	<u>Pre-Test</u>	<u>Post Test</u>
Wet Density (Lbs/ft ³)	124.8	125.6
Dry Density (Lbs/ft ³)	96.5	97.6
Moisture (% Dry Wt)	29.3	28.7
Porosity (n)	.43	.42
Degree of Saturation (%)	1.0	1.0
Specific Gravity (ASTM D-854)	2.70	---

Permeability

Temperature Correction, $R_t = 1.041$

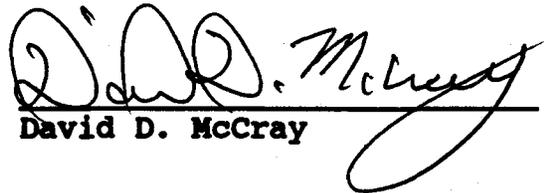

- $K_1 = 4.6 \times 10^{-6}$ cm/sec
- $K_2 = 4.0 \times 10^{-6}$ cm/sec
- $K_3 = 5.1 \times 10^{-6}$ cm/sec
- $K_4 = 4.7 \times 10^{-6}$ cm/sec

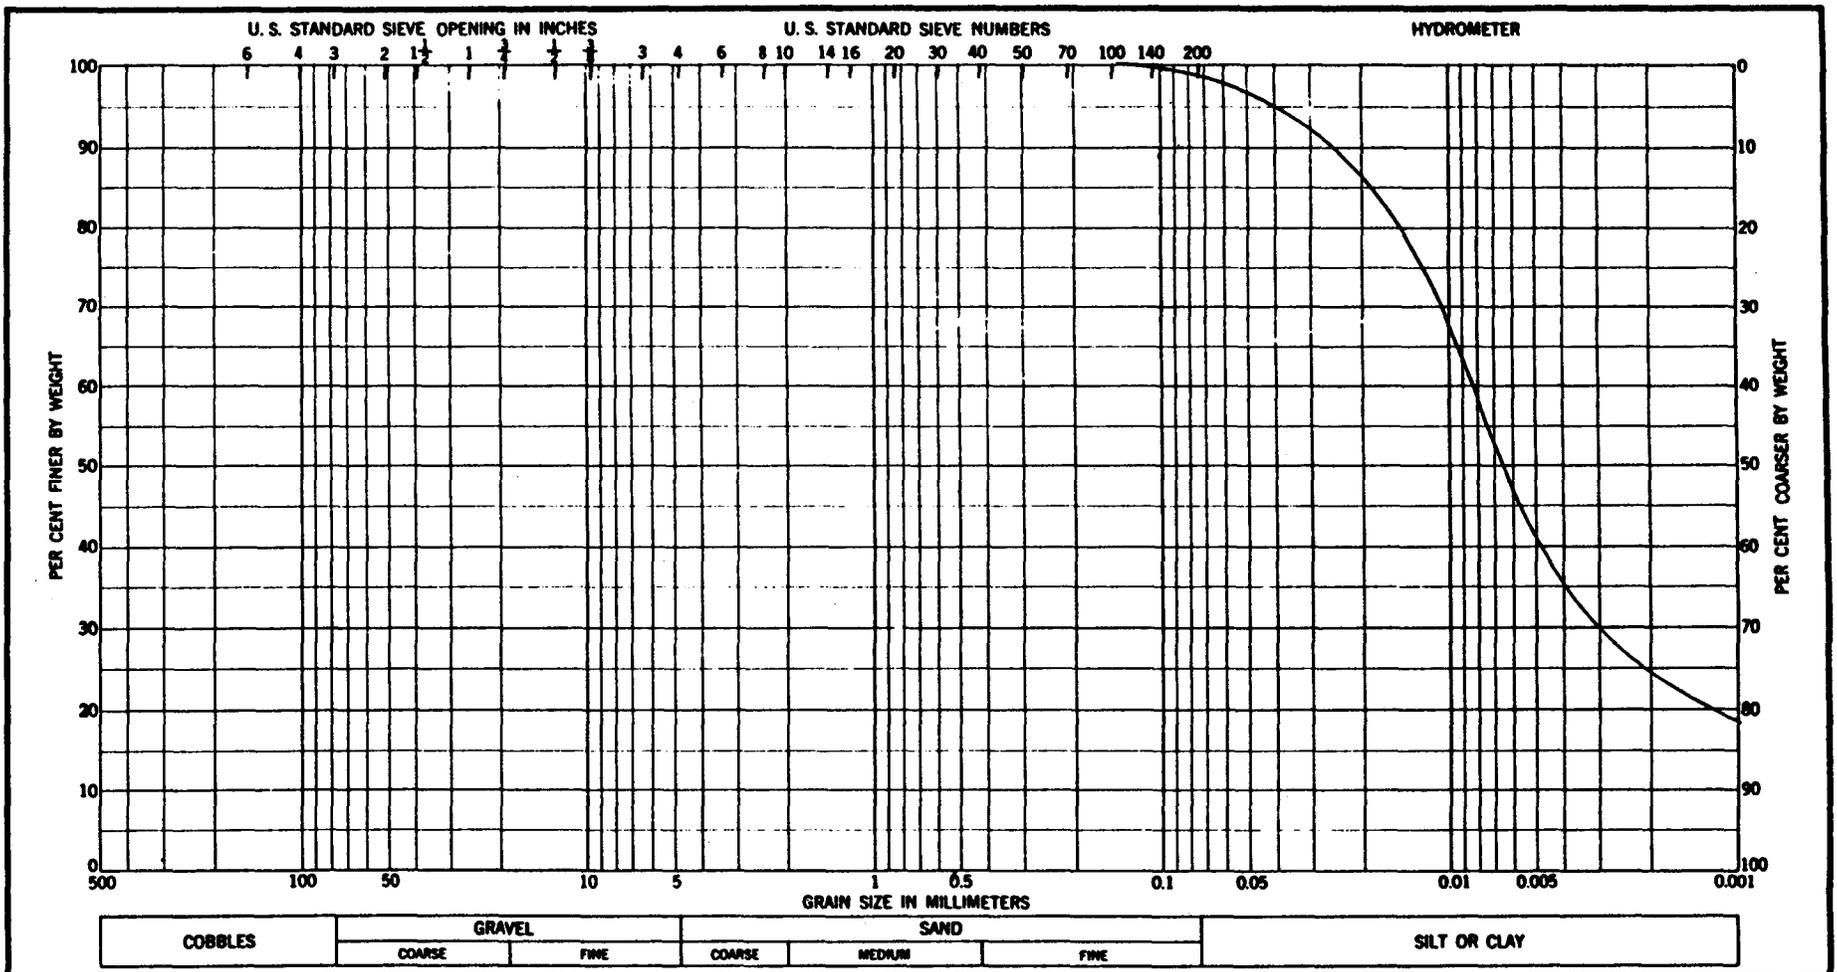

Coefficient of Permeability, $K_{20} = 4.8 \times 10^{-6}$ cm/sec

Tested in accordance with ASTM D-5084-90.

Lab No. P-96-012

MEMORANDUM

TO: Rob Williamson
NSA Memphis Public Works Environmental Division

Mark Taylor
SOUTHNAVFACENCOM

FROM: Robert Smith ^{RS}
EnSafe/Allen & Hoshall

SUBJECT: Characterization of Investigation-Derived Waste from Assembly E
SWMUs: NSA Memphis RFI, Millington, Tennessee; CT0-106

DATE: October 14, 1996

Beginning in November 1995, EnSafe/Allen & Hoshall conducted a RCRA Facility Investigation at Naval Support Activity (NSA) Memphis. Investigation derived waste (IDW) was generated during the investigation.

The IDW consisted of two types of media: soil/formation material, and water. The water was generated from activities such as decontamination of soil and groundwater sampling equipment, development of groundwater monitoring wells, and purging of the monitoring wells prior to sampling. The water was contained in a 2,000 gallon polyethylene tank at Facility S-775. Each time the tank reached its capacity, a sample was collected by E/A&H for analysis by an offsite laboratory for waste characterization parameters. The analytical results from the IDW characterization were then submitted to the City of Millington's contracted engineer, Mr. James Cox of Fisher & Arnold Engineering for discharge approval. Upon receiving discharge approval from Mr. Cox, the contents of the tank were discharged to the sanitary sewer system via an onsite oil/water separator. The 2,000 gallon tank has been cycled a total of 13 times since the beginning of the Assembly E investigation.

The second media type, soil/formation material, was generated during drilling activities, which included drilling spoils and soil/mud generated during the decontamination of the drilling and sampling equipment. Formation material consisted of all subsurface material (sand, gravel, clay) brought to the surface during the drilling/sampling activities. All material generated was containerized in 168 DOT-approved, lined, 55-gallon drums, and were properly labeled and staged in the NSA Memphis IDW storage area (Facility N-1665), where they presently remain. During a recent inspection of the IDW containers, E/A&H found that all labels

placed on the drums have become illegible preventing the correlation of individual drums with specific boring locations. This IDW characterization has been conducted as a basis for disposal and is based the on the concentrations of compounds detected in the Assembly E soil borings.

CHARACTERIZATION

A total of 101 compounds were detected during the Assembly E RFI Investigation. Each compound has been characterized based on the U.S. Environmental Protection Agency (USEPA) Hazardous Waste Rules as outlined in Title 40 of the Code of Federal Regulations, Part 261 (40 CFR 261), and the guidelines set forth by Tennessee Department of Environment and Conservation (TDEC), Division of Solid Waste Management (DSWM).

Of the 101 compounds detected, the following six compounds were defined in 40 CFR 261.30 as being "F-listed" hazardous wastes. F-listed wastes, by definition, are compounds from specific sources, which have been listed due to their Hazard Code (i.e., Toxicity, Ignitability, Corrosivity). The criteria for the selection of these compounds, as well as the USEPA Region III Risk-Based Concentration (RBC) and pertinent ignitability data, is presented in Table 1:

Table 1
NSA Memphis RFI; Assembly E IDW Characterization
F-Listed Wastes

Compound	Hazardous Waste Code as defined in 40 CFR 261	Maximum Detected Concentration ($\mu\text{g}/\text{kg}$)	Residential RBC ($\mu\text{g}/\text{kg}$)	Flashpoint (Ignitability) ($^{\circ}\text{C}/^{\circ}\text{F}$)	Selection Criteria as defined in 40 CFR 261
Trichloroethylene	F001	19.0	58,000	N/A	Toxicity
Methylene Chloride	F002	5.0	85,000	N/A	Toxicity
Tetrachloroethene	F002	23.0	12,000	N/A	Toxicity
4-methyl-2-pentanone (MIBK)	F003	170	N/A	17.8 $^{\circ}\text{C}/64^{\circ}\text{F}$	Ignitability
Acetone	F003	48000	7,800,000	0 $^{\circ}\text{C}/0^{\circ}\text{F}$	Ignitability
2-butanone (MEK)	F005	3600	47,000,000	-8.75 $^{\circ}\text{C}/16^{\circ}\text{F}$	Ignitability, Toxicity

Notes:

N/A = Data not available

According to 40 CFR 261.3(a)(2)(iii), "A solid waste, as defined in § 261.2, is a hazardous waste if....it is a mixture of a solid waste and a hazardous waste that is listed in Subpart D of this part solely because it exhibits one or more of the characteristics of hazardous waste identified in subpart C of this part, *unless the resultant mixture no longer exhibits any characteristics of hazardous waste identified in subpart C of this part.....*"

According to 40 CFR 261.30, the F001 and F002 wastes (trichloroethylene, methylene chloride, and tetrachloroethene) were listed due to their toxicity, and the F005 waste (MEK) was listed due to its toxicity and ignitability. Also, according to 40 CFR 261.30, the F003 (MIBK and Acetone)

wastes were listed due to their ignitability. Because of the low contaminant concentrations detected and the medium (i.e., soil) in which they are contained, soil found at the Assembly E SWMUs does not exhibit the ignitable characteristic. However, because toxicity cannot be physically defined as ignitability can, it would be difficult to prove that the soil/F001, soil/F002, and soil/F005 mixtures are not toxic.

The Land Disposal Restriction (LDR) Guide #5 provides the following discussion of the Contained-In Interpretation (USEPA Office of Solid Waste Management dated November 13, 1986). "The contained-in policy states that any mixture of a non-solid waste and a RCRA listed hazardous waste must be managed as a hazardous waste as long as the material contains (i.e., is above health based levels) the listed hazardous waste." The contained in policy was developed to address contaminated environmental media (i.e., soil, groundwater, surface water), as opposed to the mixture rule which governs mixtures of hazardous and solid wastes. E/A&H has previously confirmed that TDEC's DSWM concurs with and applies the USEPA contained-in policy using RBCs as health-based levels.

Characterization of the soil/formation material generated during the RFI will be based on the contained in policy. Past disposal of soil at NSA Memphis has also applied the contained-in policy in this situation (Memorandum, *Characterization of Investigation Derived Waste from Assembly A SWMUs*; CTO-094; June 6, 1995). A comparison of the soil boring data to the residential RBCs for soil (Table 1) shows that the maximum concentrations of the potentially listed hazardous wastes contained in the IDW do not exceed the health-based risk levels.

Petroleum Constituents

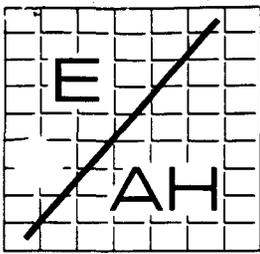

As part of the full scan analytical parameter list associated with the investigation, each sample collected was submitted for total petroleum hydrocarbon (TPH) analysis using the Tennessee-

modified USEPA methods 8015 for gasoline range organics (GRO) and diesel range organics (DRO). The maximum detected concentrations of TPH-GRO and TPH-DRO were 260 mg/kg and 650 mg/kg, respectively; however, the average detected concentrations of TPH-GRO and TPH-DRO were 7.5 mg/kg and 49.8 mg/kg, respectively; with 4% of the samples analyzed exceeding 100 mg/kg TPH. Because labels on the drums containing the IDW are illegible, individual sample results cannot be correlated to the representative IDW on a drum by drum basis. Therefore, all IDW must be characterized together as one unit; for this reason, the average of all detected results was used in the characterization process. Based on the low average concentration of petroleum constituents detected, and the infrequency of detections exceeding 100 mg/kg of TPH, the material would not meet the TDEC DSWM criteria for a petroleum contaminated soil of 100 mg/kg TPH.

NON-HAZARDOUS IDW DISPOSAL

Options for the disposal of the non-hazardous IDW include:

1. All soil and formation material can be spread or buried at an existing SWMU (e.g., Salvage Yard #2, SWMU 41) on property being retained by the Navy, preferably in a single, predetermined area to facilitate future locating and sampling of the material, if necessary. The spreading of this material at an existing SWMU would eliminate the potential for creating a future SWMU and material handling activities should blend the IDW, creating a more homogeneous mixture, which would be more representative of the average concentrations discussed previously.
2. All soil can be sent to a TDEC-approved, non-hazardous landfill.

Memorandum

Date: January 24, 1997
To: NSA Memphis, BRAC Cleanup Team
From: Robert Smith, E/A&H/RS
Re: Assembly E IDW Drum Screening Results

E/A&H has recently completed the drum screening activities associated with the NSA Memphis Assembly E investigation derived waste (IDW). The drum screening, conducted at the request of the BCT, was in response to the *Characterization of Investigation-Derived Waste from Assembly E SWMUs* memorandum (E/A&H, October 14, 1996) which stated that 4% of the samples collected during the Assembly E RFI contained petroleum hydrocarbon concentrations exceeding 100 mg/kg.

The screening activities were conducted following the procedures outlined in the *Drum Screening Procedures, Assembly E IDW* memorandum (E/A&H, December 9, 1996) presented to the BCT, with one procedural change made at the request of Mr. Jim Morrison (Tennessee Department of Environment and Conservation [TDEC]). In addition to collecting headspace data from each drum, a sample was also collected from each drum and placed in an air tight bag (i.e., zip-lock), and the contents of the bag were subsequently screened using a flame ionization detector (FID).

At the request of TDEC, their office was notified prior to beginning any screening activities; however, due to technical difficulties associated with the instruments (i.e., PID, FID), no work was performed while TDEC was on site.

The data, presented in the attached table and associated graph, indicate that 6 out of the 160 (3.75%) drums screened exhibited elevated organic vapor concentrations in relation to the rest of the drums. Due to varying factors associated with organic vapor readings and containerized soil (i.e., painted surfaces on the interior of the drum, moisture, etc.), the organic vapor levels detected may or may not be indicative of the petroleum concentration of the drum contents.

The available disposal options for the Assembly E IDW include onsite disposal (identical to the Assembly A IDW), however, the petroleum levels in the soil may need to be confirmed by collecting samples of the material contained in the 6 drums exhibiting elevated headspace readings. If the BCT decides the data is needed, composite samples will be collected from each drum using a stainless steel hand auger to allow the samplers to obtain material from 3 points within the material contained in each drum. These composite samples, a total of 6, would be submitted for total petroleum hydrocarbon analysis by EPA Method 418.1.

Should the analytical data indicate that the petroleum levels of any of the drums exceed the current TDEC definition of a petroleum contaminated soil (presently 100 ppm TPH), that drum will be segregated for disposal under the TDEC Special Waste Policy. The remaining soil may be spread onsite, at a location agreed upon by the NSA Memphis Public Works Office and the BCT.

**Technical Memorandum —
General Human Health Risk Assessment**

TECHNICAL MEMORANDUM

TO: Mark Taylor/David Porter, SOUTHDIV
Tonya Barker/Rob Williamson, NSA Memphis
Brian Donaldson, USEPA
Jim Morrison, TDEC
Jack Carmichael, USGS
Brenda Duggar, MSCHD
E/A&H Project Team

FROM: Brian Mulhearn, E/A&H

DATE: February 4, 1997

RE: **Revision 1 General Human Health Risk Assessment (HHRA) Approach
for NSA Memphis**

This memorandum discusses the general HHRA approach for NSA Memphis and incorporates USEPA's suggestions received during the January 28, 1997 Base Realignment and Closure (BRAC) Cleanup Team meeting. This text will not be reproduced in subsequent HHRAs with the exception of the final report, where the text will be included as an appendix. Initially, HHRAs will include only site-specific information and will reference this memorandum, reducing the bulk necessary to present site-specific risk information to risk managers. Deviations from these general methods will be justified and discussed in site-specific HHRAs.

1 BASELINE RISK ASSESSMENT

1.1 Introduction

A baseline risk assessment (BRA) establishes a baseline of risk to facilitate risk management decisions. Risk is the estimated potential for toxic effects on actual or hypothetical human or ecological receptors, while baseline risk refers to risk arising from exposures to chemicals assuming site conditions remain unchanged. BRAs are used by risk managers to decide if remedial actions are necessary and to determine the extent of remediation necessary to reduce the risk to acceptable levels. Generally, a BRA is divided into two sections, one assessing human health risk, and a second addressing ecological risk. This section addresses generally applied HHRA methods, while ecological risk assessment methods will be addressed in the site-specific assessments. Data management and analysis methods which will be used to reach the conclusions of site-specific HHRAs are discussed below. The following sections describe the methods, procedures, considerations, toxicological information, and related uncertainties possibly affecting HHRAs at NSA Memphis.

1.2 Background

The site background will be summarized in this section of the site-specific HHRAs.

2 General Guidance

HHRAs will generally be prepared in accordance with the guidelines set forth in the following documents, although some may not apply to every site:

- *Provisional Guidance for Quantitative Risk Assessment of PAHs*, U.S. Environmental Protection Agency, ECAO-CIN-842, EPA/600/BP92/001C, July 1993.
- *Risk Assessment Guidance for Superfund (RAGS), Volume I – Human Health Evaluation Manual, Part A*, U.S. Environmental Protection Agency/Office of Emergency and Remedial Response (OERR), EPA/540/1-89/002, December 1989 (Interim).

- *RAGS, Volume I — Human Health Evaluation Manual, (Part B, Development of Risk-Based Preliminary Remediation Goals)*, USEPA/OERR, EPA/540/R92/003, December 1991 (Interim).
- *RAGS, Volume I — Human Health Evaluation Manual, Supplemental Guidance — Standard Default Exposure Factors — Interim Final*, EPA/OERR, Office of Solid Waste and Emergency Response (OSWER) Directive: 9285.6-03, March 25, 1991. (RAGS Supplement).
- *RAGS, Volume I — Human Health Evaluation Manual, Supplemental Guidance-Dermal Risk Assessment — Interim Guidance*, EPA/OERR, August 18, 1992. (Supplemental Dermal Guidance).
- Supplemental Guidance to RAGS: Region IV Bulletin, *Development of Health-Based Preliminary Remediation Goals, Remedial Goal Options (RGO) and Remediation Levels* (Supplemental RGO Guidance).
- Supplemental Guidance to RAGS: Region IV Bulletin, *Provisional Guidance of Quantitative Risk Assessment of PAHs* (EPA Document EPA/600/R-93-089 July 1993).
- *Supplemental Guidance to RAGS: Calculating the Concentration Term*, May 1992.
- USEPA Region III *Selecting Exposure Routes and Contaminants of Concern by Risk-Based Table*, March 18, 1994, (RBC Screening Tables).
- USEPA Region III *Risk-Based Concentration Table*, January 1995, and subsequent versions (USEPA 1995).

2.1 Objectives

The objectives of the BRA will be to:

- Characterize the source media and determine the chemicals of potential concern (COPCs) for affected environmental media.
- Identify potential receptors and quantify their potential exposures under current and future conditions for all affected environmental media.
- Qualitatively and quantitatively evaluate the adverse effects associated with the site-specific COPCs in each medium.
- Characterize the baseline carcinogenic and noncarcinogenic risks associated with exposure to environmental media at the site(s) under current and future land use conditions.
- Evaluate the uncertainties related to exposure predictions, toxicological data, and resulting carcinogenic risk and noncarcinogenic hazard estimations.
- Establish Remedial Goal Options (RGOs) for chemicals of concern (COC) in each environmental medium based on risk/hazard to facilitate risk management decision-making.

The value of the risk assessment as a basis for making remedial decisions and determining whether detected site concentrations have the potential for toxic effects or increased cancer incidences depends upon adequately characterizing chemical contamination. Variables considered in characterizing the study area and its associated risk will include the amount, type, and location of sources; the pathways of exposure (media type and migration routes); and the type, sensitivities, exposure duration, and dynamics of the exposed populations (receptors). Sampling activities

typically consist of collecting surface (0 to 1-foot interval) and subsurface soil samples, and groundwater samples from monitoring wells installed in various water-bearing zones.

2.2 Organization

A human health risk assessment, as defined by RAGS Part A, includes the following steps:

- *Site characterization:* evaluation of data regarding site geography, geology, hydrogeology, climate, and demographics.
- *Data collection:* analysis of environmental media samples, including background/reference samples.
- *Data evaluation:* statistical analysis of analytical data to identify the nature and extent of contamination and to establish a preliminary list of COPCs based on risk-based and background screening. This list will subsequently be refined to identify COCs.
- *Exposure assessment:* identification of potential receptors under current and predicted conditions and potential exposure pathways, and calculation/quantitation of exposure point concentrations and chemical intakes.
- *Toxicity assessment:* qualitative evaluation of the adverse effects of the COPCs, and quantitative estimate of the relationship between exposure and severity or probability of effect.
- *Risk characterization:* combination of the output of the exposure and the toxicity assessments to quantify the total noncancer and cancer risk to the hypothetical receptors.

- *Uncertainty*: discussion and evaluation of the areas of recognized uncertainty in human health risk assessments in addition to medium - and exposure pathway-specific influences.
- *Risk/hazard summary*: presentation and discussion of the results of the quantification of exposure (risk and hazard) for the potential receptors and their exposure pathways identified under the current and future conditions.
- *RGOs*: computation of exposure concentrations corresponding to risk projections within the USEPA target risk range of 1E-6 to 1E-4 for carcinogenic COCs and hazard quotient goals of 0.1, 1, and 3 for noncarcinogenic COCs.

3 Site Characterization

When performing a HHRA, environmental media data are compiled to determine potential site-related chemicals and exposures as outlined in RAGS Part A. The steps identifying COPCs are discussed below.

3.1 Data Sources

The number of samples collected from each medium will be detailed in this section of the site-specific HHRA, and tables will show which sample designations will be included and how data are grouped (when applicable). In addition, the analytical methods, the name of the analyzing laboratory, and data quality objectives will be referenced at this point in the HHRA.

3.2 Data Validation

Data validation is an after-the-fact, independent, systematic process of evaluating data and comparing them to established criteria to confirm they are of the technical quality necessary to support the decisions made in the RFI process. Parameters specific to the data are reviewed to determine whether they meet the stipulated DQOs. The quality objectives address five principal

parameters: precision, accuracy, completeness, comparability, and representativeness. To verify that these objectives are met, field measurements, sampling and handling procedures, laboratory analysis and reporting, and nonconformances and discrepancies in the data are examined to determine compliance with appropriate and applicable procedures.

Data for NSA Memphis will be validated in accordance with the methods outlined in the *Comprehensive RFI Work Plan (E/A&H, 1994b)*. The data validation report will be referenced in this section of the HHRA.

3.3 Management of Site-Related Data

All environmental sampling data will be evaluated for suitability for use in the quantitative BRA. Data obtained via the following methods will be considered inappropriate:

- Analytical methods that are not specific for a particular chemical, such as total organic carbon, total organic halogen, or TPH (design parameter samples).
- Field screening instruments including total organic vapor monitoring units and organic vapor analyzers.

Additional data excluded will be detailed in the site-specific HHRAs.

Limitations of analytical results will be addressed in HHRAs by including estimated concentration values for reported nondetects. A nondetect indicates that the analyte was not detected above the practical quantitation limit of the sample ("U" qualified results), which is determined by the analytical method, the instrument used, and possible matrix interferences. However, a nondetected analyte could exist at a concentration between zero and the quantitation limit. For this reason, one-half the "U" value could serve as an unbiased estimate of the nondetect. Because the

estimated values of "J" qualified hits are frequently much lower than the sample quantitation limits of "U" qualified nondetects for organic compounds, one-half of each "U" value will be compared to one-half of the lowest hit (normally "J" qualified) at the same site. The lesser of these two values will be used as the best estimate of the concentration potentially present below the sample quantitation limit, and will be inserted into the adjusted dataset. For inorganic chemicals, the rule is simpler: One-half of each "U" value will be used to represent the concentration of the corresponding sample when compiling the adjusted dataset. If two nondetects are reported for any one location (a result of QA/QC samples), one-half the lesser of the "U" values will be compared to the lowest hit at the site (for organics, as above) or applied directly (for inorganics) to estimate a concentration value to be used in the NSA Memphis risk calculations. If a parameter is not detected at a site, neither data management method will be applied, and the parameter will not be considered in screening or formal assessment.

Once the dataset is complete, statistical methods will be used to evaluate the analytical results to (1) identify COPCs and (2) establish exposure point concentrations (EPCs) at potential receptor locations. The statistical methods used in data evaluation are discussed below. The rationale used to develop this methodology and the statistical techniques is based on the following sources:

- RAGS Part A
- *Supplemental Guidance to RAGS: Calculating the Concentration Term*, May 1992
- *Statistical Methods for Environmental Pollution Monitoring* (Gilbert, 1987)

Microsoft Fox Pro and Borland¹ Quattro Pro will typically be used for data management and statistical calculations. For each set of data used to describe the concentration of chemicals in a contaminated area, the following information will be tabulated in accordance with RAGS:

¹ *References to specific software products are not to be construed as an endorsement by the U.S. Navy or E/A&H.*

frequency of detection, range of quantitation limits, range of detected values, and average of detected concentrations. For datasets of 10 or more, the upper confidence limit (UCL) on the mean of log-transformed values of the concentration will be presented. In accordance with RAGS, the lesser of either the maximum concentration detected or the UCL will be used to quantify potential exposure, as detailed in Section 4, Exposure Assessment.

3.4 Selection of COPCs

The substances detected (chemicals present in site samples, or CPSSs) will be screened to develop a list or group of COPCs. COPCs are, therefore, chemicals selected by comparison to screening concentrations, intrinsic toxicological properties, persistence, fate and transport characteristics, and cross-media transport potential. The nature and general extent of CPSSs will be referenced in this section of the site-specific HHRAs. To reduce the list of CPSSs and focus the risk assessment on COPCs, the following two comparisons will be performed.

3.4.1 Comparison of Site-Related Data to Risk-Based Screening Concentrations

The maximum concentrations of CPSSs detected during sampling will be compared to risk-based screening values. These values will be obtained from *Risk Based Screening Concentrations*, USEPA Region III, January through June, 1996 (and subsequent versions). As stated in the EPA Region III document, a risk goal of 1E-6 will be used to calculate screening concentrations for carcinogens. RBCs will be adjusted to reflect a target HQ of 0.1 for noncarcinogens, in accordance with USEPA Region IV *Supplemental Guidance to RAGS Bulletin 1* (USEPA, November 1995). Groundwater results will be compared to tap water screening values, and reported soil concentrations will be compared to residential soil screening values. CPSSs with maximum detected concentrations exceeding their corresponding concentrations, goals, levels, and/or standards will be evaluated further and compared to reference background concentrations. In addition, surrogate screening values based on toxicological similarities will be used if no screening value are available in USEPA's table, and surrogate screening values will be noted where applied.

The maximum concentration reported for each carcinogenic polycyclic aromatic hydrocarbon (PAH) will be compared to its corresponding screening value. In addition, all carcinogenic PAH concentrations reported at that location will be converted to the benzo(a)pyrene equivalent concentration (BEQ), which will be compared to the screening value for benzo(a)pyrene. PAH conversions will be performed using current Toxic Equivalency Factors (TEFs) for PAHs in accordance with USEPA Region IV *Supplemental Guidance to RAGS Bulletin 2* (USEPA, November 1995).

3.4.2 Comparison of Site-Related Data to Background Concentrations

Background data for NSA Memphis will be referenced in this section, or background reference concentrations from E/A&H's August 27, 1996 *Reference Concentrations* technical memorandum will be used. Following comparison to risk- and hazard-based screening values, CPSSs whose maximum detected concentrations exceeded corresponding background reference concentrations will be formally assessed in the HHRA, unless otherwise noted.

The maximum reported concentration of a CPSS will be compared to its reference background concentration (when applicable). This comparison helps account for naturally occurring elements, such as beryllium, manganese, and arsenic. Thus, risk and/or hazard associated with naturally occurring elements are not addressed where their concentrations are similar to corresponding background.

In the HHRA, if the maximum concentration of a CPSS is determined to be less than either two-times mean background or the risk-based screening values, then the CPSS will not be considered further unless deemed appropriate based on chemical-specific characteristics (e.g., degradation product with greater toxicity).

3.4.3 Elimination of Essential Elements: Calcium, Iron, Magnesium, Potassium, and Sodium

In accordance with RAGS Part A, essential elements that are potentially toxic only at extremely high concentrations may be eliminated as COPCs in a risk assessment. Specifically, an essential nutrient may be screened out if it is present at concentrations that are not associated with adverse health effects. Based on RAGS, the lack of risk-related data, and USEPA Region IV's recommendations, the following essential nutrients will not be included in HHRAs: calcium, iron, magnesium, potassium, and sodium.

Risk information usually obtained from the Integrated Risk Information System (IRIS) or Health Effects Assessment Summary Tables (HEAST) is necessary to calculate risk and hazard estimates (and risk-based screening values). This information is based on toxicological and epidemiological data which are critiqued and approved by the scientific and regulatory community (i.e., listed in IRIS and/or HEAST). Risk information (or surrogate risk information) is not always available for all CPSSs, so their risk and/or hazard will not be calculated. The results of the screening process will be tabulated in the HHRA. No risk-based screening values are available for TPH and chemical-specific analyses were performed on site samples, so exposure will not be quantified for this group of compounds. The most toxic TPH constituents would generally be included in the chemical-specific analyses.

3.4.4 Summary of COPCs

The results of the screening evaluations will be tabulated on a medium-specific basis in the site-specific HHRAs.

3.5 Estimation of Risk and Hazard

COPCs will be identified, and exposure will be estimated for these compounds. Risk/hazard will be subsequently calculated based on exposure estimates, then exposure scenarios (e.g., soil

exposure during commercial land use) exceeding USEPA acceptable limits will be identified. An exposure scenario of concern will be identified as a scenario with incremental excess lifetime cancer risk (ILCR) estimated greater than $1E-4$ or a hazard index (HI) estimated greater than 1. In the next step, COPCs exceeding $1E-6$ ILCR or a HQ greater than 0.1 in a scenario of concern are retained as COCs. Section 5, Toxicity Assessment, discusses cancer risk thresholds and noncancer toxicity in detail.

4 Exposure Assessment

This section of the HHRAs will determine the magnitude of contact that a potential receptor may have with site-related COPCs. Exposure assessment involves four stages:

- Characterizing the physical setting and land use of the site.
- Identifying COPC release and migration pathway(s).
- Identifying the potential receptors, under various land use or site condition scenarios, and the pathways through which they might be exposed.
- Quantifying the intake rates, or contact rates, of COPCs.

4.1 Exposure Setting and Land Use

The site setting and land use will be detailed or referenced in this section of the site-specific HHRAs. This information is used to develop appropriate exposure estimates for different land use assumptions. If the future use of the area in question is known, this information will be used to define exposure assumptions used when calculating risk (e.g., sites known to be commercially zoned will not be assessed for residential land use). Future land use will be specified with as much accuracy as possible in site-specific HHRAs, particularly for property being transferred from the Navy to the City of Millington.

4.2 Potentially Exposed Populations

This section will describe who may be exposed to contaminants in environmental media. The populations typically addressed will be one or a combination of the following: current site workers, hypothetical current site trespassers, as well as hypothetical future site residents. Because current site workers at most sites within NSA Memphis would be expected to have limited contact with contaminated media at most sites, worker-related exposure may be addressed exclusively for maximally exposed site workers, assuming the future worker scenario would be protective of both current and future site workers. Specifics will be discussed in this section of the site-specific HHRA.

4.3 Exposure Pathways

This section will summarize how potential human receptors may be exposed to site media. In general, soil matrix-related pathways will include incidental ingestion and dermal contact. Ingestion and inhalation of volatilized contaminants will be typical groundwater exposure pathways. The hypothetical future scenarios will assume continuous, uniform exposure to current surface soil conditions and the use of site groundwater as a potable water source, unless otherwise noted in the site-specific HHRA. A table in the site-specific HHRA will justify and summarize exposure pathways and potential human receptors.

4.4 Exposure Point Concentrations

The EPC is the estimated concentration of a contaminant in an exposure medium that will be contacted by a real or hypothetical receptor. Determining the exposure point concentration depends on factors such as:

- Availability of data
- Amount of data available to perform statistical analysis
- Reference concentrations not attributed to site impacts
- Location of the potential receptor

USEPA Region IV guidance calls for assuming lognormal distributions for environmental data and the calculation of 95% UCL on the mean for use in exposure quantification. Applying the UCL is generally inappropriate with less than 10 samples. Therefore, the maximum concentrations detected will be used for all datasets with less than 10 samples. In general, outliers have been included when calculating the UCL because high values seldom appear as outliers for a lognormal distribution. Including outliers increases the overall uncertainty of the calculated risks and conservatively biases exposure estimates.

For sample sets of 10 and greater, the UCL will be calculated for a lognormal distribution as follows:

$$UCL = e^{\left(\bar{a} + 0.5s_a^2 + \frac{H_{0.95} x s_a}{\sqrt{n-1}} \right)}$$

where:

- \bar{a} = $\Sigma a/n$ = sample arithmetic mean of the log-transformed data, $a = \ln(x)$
- s_a = sample standard deviation of the log-transformed data
- n = number of samples in the data set
- $H_{0.95}$ = value for computing the one-sided upper 95% confidence limit on the lognormal mean from standard statistical tables (Gilbert, 1987)

EPCs and UCLs will be summarized and tabulated when applicable in the site-specific HHRA.

4.5 Quantification of Exposure

This section describes the models, equations, and intake model variables used to quantify doses or intakes of the COPCs for the surface soil and groundwater exposure pathways. The models are

designed to estimate route- and medium-specific factors, which are multiplied by the EPC to estimate chronic daily doses. The intake model variables generally reflect 50th or 95th percentile values which, when applied to the EPC, ensure that the estimated intakes represent the reasonable maximum exposure (RME, which is considered 95th percentile). Formulae are derived from RAGS, Part A unless otherwise indicated. Table 1 lists intake model variables used to compute chronic daily intake (CDI) for potential receptors exposed to surface soil and/or groundwater contaminants.

Because NSA Memphis is part of BRAC, future site use cannot be determined with any certainty. Therefore, the conservative assumptions will be used to account for any reasonable future use. Current reuse plans will be referenced and discussed in the site-specific HHRAs. NSA Memphis media analytical results and exposure methods have been formatted to allow exposure estimates to be fine-tuned based on actual conditions as base reuse plans materialize, and this information will be used on a site-specific basis, if known.

In accordance with USEPA's recommendations, the adult and child intake variables will be combined to estimate exposure to carcinogens. This factor is referred to as the lifetime weighted average, or LWA. The LWA considers the difference in daily ingestion rates for soil and drinking water, body weights, and exposure durations for children (ages 1 to 6) and adults (ages 7 to 31). The exposure frequency is assumed to be identical for the adult and child exposure groups, and an example is shown after the equations are presented below.

Before quantifying soil exposure, it will first be necessary to derive the appropriate fraction ingested (or contacted) (FI/FC) from contaminated area factors for each applicable COPC. These factors will be derived by evaluating the spatial distribution of COPCs. The FI/FC will be computed by estimating the maximum area affected and dividing it by the total exposure unit area. These computations will be performed conservatively to account for uncertainty associated with contaminant distributions.

Table 1
Parameters Used to Estimate CDI

Pathway Parameters	Resident Adult	Resident Child	Adult Worker	Trespassing Child (age 7-16)	Units
Surface Soil Ingestion and Dermal Contact					
Ingestion Rate (soil)	100 ^a	200 ^a	50 ^a	100 ^a	mg/day
Ingestion Rate (water)	2	1	1	NA	L/day
Exposure Frequency	350 ^b	350 ^b	250 ^b	52 ^f	days/year
Exposure Duration	24 ^c	6 ^c	25 ^c	10 ^g	years
Dermal Contact Area	4,100 ^a	2,900 ^a	4,100 ^a	4,100 ^a	cm ²
Skin Adherence Factor	1	1	1	1	mg/cm ²
Absorption Factor	0.01 (organics) 0.001 (inorganics)	0.01 (organics) 0.001 (inorganics)	0.01 (organics) 0.001 (inorganics)	0.01 (organics) 0.001 (inorganics)	unitless
Oral Absorption Efficiency	0.8 (VOCs) 0.5 (other organic compounds) 0.2 (inorganics)	unitless			
Conversion Factor	1E-6	1E-6	1E-6	1E-6	kg/mg
Body Weight	70 ^a	15 ^a	70 ^a	45 ^a	kg
Averaging Time, Noncancer	8,760 ^d	2,190 ^d	9,125 ^d	3,650 ^d	days
Averaging Time, Cancer	25,550 ^e	25,550 ^e	25,550 ^e	25,550 ^e	days

Notes:

- a — USEPA (1989a) *Risk Assessment Guidance for Superfund Vol. 1, Human Health Evaluation Manual (Part A)*.
- b — USEPA (1991b) *Risk Assessment Guidance for Superfund Vol. 1: Human Health Evaluation Manual Supplemental Guidance, Standard Default Exposure Factors, Interim Final, OSWER Directive: 9285.6-03.EPA/600/8-89/043*.
- c — USEPA (1991a), *Risk Assessment Guidance for Superfund: Vol. 1 – Human Health Evaluation Manual (Part B, Development of Risk-Based Preliminary Remediation Goals)*, OSWER Directive 9285.7-01B.
- d — Calculated as the product of ED (years) x 365 days/year.
- e — Calculated as the product of 70 years (assumed lifetime) x 365 days per year.
- f — Assuming one day per week exposure.
- g — Assuming trespassing occurs during the 10-year adolescent/teenage period.
- NA — Not applicable.

The FI/FC factors modify the concentrations to more closely approximate site-wide exposure conditions for a given exposure unit area. When the UCL is used as EPC, no FI/FC adjustments will be made. In addition, CPSSs not eliminated from the HHRAs based on the screening comparisons described in Section 3.4 may be eliminated as a COPC because the UCL concentration does not exceed the corresponding background concentration or RBC. This will be discussed on a site-specific basis.

4.5.1 Surface Soil Pathway Exposure

Ingestion of COPCs in Surface Soil

Except CDI for a site resident's exposure to carcinogens, the following equation is used to estimate the ingestion of COPCs in soil:

$$CDI_s = (EPC_s)(IR)(EF)(ED)(F)(FI)/(BW)(AT)$$

where:

- CDI_s = ingested dose (mg/kg-day)
- EPC_s = exposure point concentration of contaminant in soil (mg/kg)
- IR = ingestion rate (milligrams per day [mg/day])
- EF = exposure frequency (days/year)
- ED = exposure duration (years)
- F = conversion factor (1E-6 kg/mg)
- FI = fraction ingested from contaminated source (unitless)
- BW = body weight (kg)
- AT = averaging time (days)

The LWA is used to calculate carcinogenic CDI for site residents. An example of the LWA calculation is shown below for the soil ingestion pathway, and LWAs are similarly calculated for subsequent equations.

$$LWA = [(IR_a \times ED_a)/BW_a] + [(IR_c \times ED_c)/BW_c]$$

where:

- LWA = lifetime weighted average
- IR = ingestion rate (milligrams per day [mg/day])
- ED = exposure duration (years)
- BW = body weight (kg)

- a = adult
c = child

Consequently, CDI for carcinogens would be calculated as follows for site residents:

$$CDI_s = (EPC_s)(EF)(LWA)(F)(FI)/(AT)$$

where:

- CDI_s = ingested dose (mg/kg-day)
 EPC_s = exposure point concentration of contaminant in soil (mg/kg)
EF = exposure frequency (days/year)
F = conversion factor (1E-6 kg/mg)
FI = fraction ingested from contaminated source (unitless)
AT = averaging time (days)
LWA = lifetime weighted average

Dermal Contact with COPCs in Surface Soil

The following equation is used to estimate intake due to dermal contact with COPCs in soil:

$$CDI_{sd} = (EPC_s)(CF)(EF)(ED)(F)(FC)(ABS)(AF)/(BW)(AT)$$

where:

- CDI_{sd} = dermal dose (mg/kg-day)
 EPC_s = exposure point concentration of contaminant in soil (mg/kg)
CF = contact factor (cm²)
EF = exposure frequency (days/year)
ED = exposure duration (years)
F = conversion factor (1E-6 kg/mg)
FC = fraction contacted from contaminated source (unitless)
ABS = absorption factor (unitless value, specific to organic versus inorganic compounds)

- AF = adherence factor (milligrams per square centimeter [mg/cm²])
BW = body weight (kg)
AT = averaging time (days)

4.5.2 Groundwater Pathway Exposure

Ingestion and Inhalation of COPCs in Groundwater

The following equation is used to estimate the ingestion and/or inhalation of COPCs in groundwater:

$$CDI_w = (EPC_w)(IR)(EF)(ED)(FI)/(BW)(AT)$$

where:

- CDI_w = ingested/inhaled dose (mg/kg-day)
EPC_w = exposure point concentration of contaminant in water (milligrams per liter [mg/L])
IR = ingestion rate (L/day)
EF = exposure frequency (days/year)
ED = exposure duration (years)
FI = fraction ingested from contaminated source (unitless)
BW = body weight (kg)
AT = averaging time (days)

HHRAs are comprised of many tables, and intake tables serve only as an intermediate check when reviewing the document. The CDI equations above can be solved assuming a concentration of 1, and the result can be used as a universal multiplier. Multipliers were developed for each typical land use scenario and are shown in Table 2. Consequently, a significant number of the tables in HHRAs can be eliminated. An example of the abbreviated CDI method is shown below:

$$CDI = (EPC)(M)$$

where:

- CDI = chronic daily intake (mg/kg-day)
 EPC = exposure point concentration (mg/kg or mg/L)
 M = multiplier specific to the exposure scenario, land use, and potential receptor selected

Table 2
Multipliers^a Used to Estimate Chronic Daily Intake

Exposure Scenario	Exposure Type	Soil		Groundwater
		Ingestion	Dermal Contact	Ingestion
		All Chemicals	Organics ^b	All Chemicals ^c
<i>Resident</i>	Noncarcinogens (adult)	1.37E-6	5.62E-7	2.74E-2
	Noncarcinogens (child)	1.28E-5	1.85E-6	6.39E-2
	Carcinogens (LWA)	1.57E-6	3.51E-7	1.49E-2
<i>Trespasser</i> (age 7-16)	Noncarcinogens	3.17E-7	1.30E-7	NA
	Carcinogens	4.52E-8	1.85E-8	NA
<i>Site Worker</i>	Noncarcinogens	4.89E-7	4.01E-7	9.78E-3
	Carcinogens	1.75E-7	1.43E-7	3.49E-3

Notes:

- NA — Not applicable
 LWA — Lifetime weighted average
^a — The product of the multiplier and the exposure point concentration equals the chronic daily intake for a given chemical assuming a reasonable maximal exposure scenario.
^b — The multiplier for inorganics is multiplied by a factor of 0.1 to account for the dermal absorption factor of 0.001 for inorganics; the multiplier for organic compounds includes the 0.01 factor.
^c — The ingestion intake is also used to address inhalation risk in accordance with USEPA's Supplemental Guidance To RAGS Bulletin 3; ingestion risk is approximately equal to risk posed by dermal and inhalation exposure while showering, and this is applied to volatile organic compounds only.

Because multipliers can be reviewed separately, CDI will be incorporated into the risk and hazard equations and *will not be presented* in separate tables.

5 Toxicity Assessment

5.1 Carcinogenicity and Noncancer Effects

USEPA has established a classification system for rating the potential carcinogenicity of environmental contaminants based on the weight of scientific evidence. The cancer classes are described below. Cancer weight-of-evidence class "A" (human carcinogens) means that human toxicological data have shown a proven correlation between exposure and the onset of cancer (in varying forms). The "B1" classification indicates some human exposure studies have implicated the compound as a probable carcinogen. Weight-of-evidence class "B2" indicates a possible human carcinogen based on confirmatory carcinogenic laboratory animal data. Weight-of-evidence class "C" identifies possible human carcinogens, and class "D" indicates a compound not classifiable with respect to its carcinogenic potential. A class "A" compound posing risk higher than USEPA's acceptable risk range has more weight than would a class "C" compound. There is more uncertainty in the lower classifications, so the weight-of-evidence should be used by risk managers when making risk management decisions based on cancer risk.

USEPA has established slope factors (SF) for carcinogenic compounds. The SF is defined as a "plausible upper-bound estimate of the probability of a response (cancer) per unit intake of a chemical over a lifetime" (RAGS, Part A). Upper-bound estimates are more likely to overestimate cancer potential.

In addition to potential carcinogenic effects, most substances also can produce other toxic responses at doses greater than experimentally derived threshold concentrations. USEPA has derived reference dose (RfD) values for these substances. A chronic RfD is defined as, "an estimate (with uncertainty spanning perhaps an order of magnitude or greater) of a daily exposure

concentration for the human population, including sensitive subpopulations, that is likely to be without an appreciable risk of deleterious effects during a lifetime." These toxicological values are used in risk formulae to assess the upper-bound level of cancer risk and noncancer hazard associated with exposure to a given chemical concentration.

For carcinogens, the potential risk posed by a chemical is computed by multiplying the CDI (as mg/kg-day) by the SF (in reciprocal mg/kg-day). The HQ (for noncarcinogens) is computed by dividing the CDI by the RfD. USEPA has set standard limits (or points of departure) for carcinogens and noncarcinogens to evaluate whether significant risk is posed by a chemical (or combination of chemicals). For carcinogens, the point-of-departure range is 1E-6, with a generally accepted range of 1E-6 to 1E-4. These risk values correlate with one in 10,000 (1E-4) and one in 1 million (1E-6) excess cancer incidence resulting from exposure to toxic compounds from outside the body.

For noncarcinogens, other toxic effects are generally considered possible if the HQ (or sum of HQs for a pathway-hazard index) exceeds the threshold value of 1. Although both cancer risk and noncancer hazard are generally additive only if the target organ is common to multiple chemicals, a most conservative estimate of each may be obtained by summing the individual risks or hazards, regardless of target organ. Site-specific HHRAs for NSA Memphis will take the universal summation approach for each class of toxicant. Details regarding the risk formulae applied to site data are provided in Section 6, Risk Characterization.

Critical studies used in establishing toxicity classifications by USEPA are shown in the IRIS database, which is the primary source for information necessary to estimate risk. HEAST, Fiscal Year 1995 is the secondary source for this information. In addition, USEPA's National Center for Environmental Assessment (NCEA) will be used as a source when necessary. In accordance with RAGS, a table will summarize toxicological data in the site-specific HHRAs in the form of RfDs and SFs obtained for COPCs identified in site media, as well uncertainty/modifying factors, target organs, and cancer classes (where available).

5.2 Evaluating Dermal Exposure and the Resulting Toxicity

In accordance with USEPA Region IV's *Supplemental Guidance to RAGS Bulletin 2*, dermal RfD values and SFs are derived from the corresponding oral values. As described in the supplemental guidance, the oral RfD is multiplied by an oral absorption efficiency factor (OAF), expressed as a decimal. The resulting dermal RfD is based on the absorbed dose. The RfD based on absorbed dose is the appropriate value with which to compare a dermal dose, because dermal doses are expressed as absorbed rather than administered (intake) doses. For the same reasons, a dermal SF is derived by dividing the oral SF by the OAF. The oral SF is divided rather than multiplied because SFs are expressed as reciprocal doses.

Appendix A of RAGS, Part A states that in the absence of specific data, an assumption of 5% oral absorption would be relatively conservative. *Supplemental Guidance to RAGS: Region IV Bulletin 2* indicates that in the absence of specific data, USEPA Region IV suggests an oral absorption factor of 80% for volatile organics, 50% for semivolatile organics, and 20% for inorganic chemicals. These percentages (or associated fractions) will be used in the site-specific HHRA

5.3 Toxicity Profiles for COPCs

In accordance with RAGS, toxicological summary paragraphs will be included in the body of the HHRA text for all COPCs. Most information for the profiles will be gleaned from IRIS and HEAST. Another source of information will be NCEA. Any additional references will be noted specifically in the text. The profiles will summarize adverse effects of COPCs and the amount associated with such effects.

6 Risk Characterization

Risk characterization combines the exposure assessment and toxicity assessment results to yield qualitative and quantitative expressions of risk and/or hazard for the exposed receptors. The quantitative component expresses the probability of developing cancer, or a threshold comparison

of the estimated dose with a reference dose for noncancer effects. These quantitative estimates are developed for individual chemicals, exposure pathways, transfer media, and source media, and for each receptor for all media to which one may be exposed. The qualitative component usually involves comparing COC concentrations in media with established criteria or standards for chemicals for which there are no corresponding toxicity values. The risk characterization helps guide risk-management decisions.

Generally, the risk characterization will follow the methodology prescribed by RAGS Part A, as modified by more recent information and supplemental guidance cited in the earlier sections of this memorandum. *The USEPA methods are designed to be health-protective and tend to overestimate risk rather than underestimate it. The risk results, therefore, are generally overly conservative, because risk characterization involves summing the overestimated risk estimates.*

6.1 Risk Characterization Methodology

Potential excess risks to humans following exposure to COPCs will be estimated using methods established by USEPA, when available. As discussed above, these methods are health-protective and are likely to overestimate risk. Risks from hazardous chemicals are calculated for either carcinogenic or noncarcinogenic effects. Some carcinogenic chemicals may also pose a noncarcinogenic hazard. The potential human health effects associated with chemicals that produce carcinogenic and other toxic effects will be characterized separately, as discussed below.

6.1.1 Carcinogenic Effects of Chemicals

The risk attributed to exposure to carcinogens is estimated as the probability of an individual developing cancer over a lifetime as a result of exposure to a potential carcinogen. In the low-dose range, which would be expected for most environmental exposures, cancer risk is estimated from the following linear equation (EPA, 1989a):

$$\text{ILCR} = (\text{CDI})(\text{SF})$$

where:

- ILCR = incremental lifetime excess cancer risk, a unitless expression of the probability of developing cancer, adjusted for reference incidence
- CDI = chronic daily intake, averaged over 70 years (mg/kg-day)
- SF = cancer slope factor (mg/kg-day)⁻¹

For a given pathway with simultaneous exposure of a receptor to several carcinogens, the following equation is used to sum cancer risks:

$$\text{Risk}_p = \text{ILCR}(\text{chem}_1) + \text{ILCR}(\text{chem}_2) + \dots + \text{ILCR}(\text{chem}_n)$$

where:

- Risk_p = total pathway risk of cancer incidence
- ILCR(chem_i) = incremental lifetime excess cancer risk for a specific chemical

Cancer risk for a given receptor across pathways and across media is summed in the same manner.

6.1.2 Noncarcinogenic Effects of Chemicals

The risks associated with the noncarcinogenic effects of chemicals are evaluated by comparing an exposure level or intake with a reference dose. The HQ, defined as the ratio of intake to RfD, is defined as (RAGS, Part A):

$$\text{HQ} = \text{CDI}/\text{RfD}$$

where:

- HQ = hazard quotient (unitless)
- CDI = intake of chemical (mg/kg-day)

RfD = reference dose (mg/kg-day)

Chemical noncarcinogenic effects are evaluated on a chronic basis, using chronic RfD values. An HQ of 1 indicates that the estimated intake equals the RfD. If the HQ is greater than unity, there may be a concern for potential adverse health effects.

In the case of simultaneous exposure of a receptor to several chemicals, an HI will be calculated as the sum of the HQs by:

$$HI = HQ_1 + HQ_2 + \dots + HQ_n$$

where:

HI = Hazard Index (unitless)
HQ = Hazard Quotient (unitless)

Risk and hazard projections will be summarized in tabular format on a medium- and exposure pathway-specific basis in the HHRAs.

6.2 Surface Soil Pathways

Generally, the incidental ingestion and dermal contact pathways will be characterized for surface soil. Surface soil onsite will be evaluated under scenarios and exposure pathways outlined in the site-specific HHRAs.

6.3 Groundwater Pathways

Groundwater pathways will typically consist of ingestion and inhalation of volatilized chemicals in groundwater. The site-specific HHRAs will detail the pathways which will be addressed. Most groundwater pathways are not complete because municipal water supplies are used, and this will be discussed in the HHRAs.

6.4 COCs Identified

COCs will be identified based on cumulative (all pathway) risk and hazard projected for the sites. USEPA has established a generally acceptable risk range of $1E-4$ to $1E-6$, and an HI threshold of 1.0. Any COPC that is carried through the risk assessment process and found to contribute to a scenario with an ILCR in excess of $1E-4$ or HI greater than 1 for any of the exposure scenarios evaluated in this risk assessment, and has an individual exposure pathway risk greater than $1E-6$ or exposure pathway HQ greater than 0.1, will be referred to as a COC. A table will present the COCs identified in site-specific HHRAs.

7 Risk Uncertainty

This section will discuss the uncertainty and variability inherent in the risk assessment process in addition to site-, medium-, and exposure pathway-specific influences. Overall, uncertainties associated with the initial stages of the risk assessment process become magnified when they are combined with other uncertainties. It is not possible to eliminate all uncertainties; however, recognizing the uncertainties is fundamental to understanding and subsequently using risk assessment results.

Where chronic RME estimates of risk/hazard indicated a significant threat (e.g., ILCR greater than $1E-4$) would be posed to human health, central tendency (CT) analysis may be performed. RME estimates are based on the upper bound (90th or 95th percentile) exposure assumptions, while CT estimates are based on the 50th percentile (mean or median) values. CT exposure scenarios are constructed consistent with standard CT exposure assumptions provided in *Superfund's Standard Default Exposure Factors for the Central Tendency and Reasonable Maximum Exposure-Draft* (USEPA, November 1993). CT exposure assumptions will be presented in the site-specific HHRAs, when applicable.

8 Risk Summary

Risk estimates will be presented and summarized in table form in the site-specific HHRAs.

9 Remedial Goal Options

RGOs are chemical concentrations computed to equate with specific risk and/or hazard goals that may be established for a particular site. As previously discussed, COCs are identified as any COPC that significantly contributes to a scenario of concern. RGOs will be calculated for each land use scenario with cumulative risk estimates greater than $1E-4$ or cumulative hazard indices greater than 1.0. Based on this method, COCs may be identified, requiring RGO calculation. Inclusion in the RGO table does not necessarily indicate that remedial action will be required to address a specific chemical. Instead, RGOs are provided to facilitate risk-management decisions.

In accordance with USEPA Supplemental RGO Guidance, RGOs will be calculated at $1E-4$, $1E-5$, and $1E-6$ risk levels for carcinogenic COCs and HI goals of 3, 1, and 0.1 for noncarcinogenic COCs. RGOs will be based on specific scenarios which will be identified in the site-specific HHRAs.

- Notes:
- LD50 = Dose resulting in 50% mortality in test population.
 - BW = Body weight.
 - LOAEL = Lowest Observed Adverse Effect Level.
 - NR = Not reported.
 - a = Converted to dose per kilogram body weight by multiplying by ingestion and dividing by body weight.
 - b = Estimated by applying a LOAEL-NOAEL ratio of 5 (Newell et al., 1987).

			1	42	BG			(0-33') Upper Alluvium (see descriptions below).	264.2	
			2	71	BG			(0-1') Fill and skeet fragments.		
			3	73	BG			(1-24') Silt, clayey (see descriptions below).		
5			4	83	BG			(1-2') Clayey silt, yellowish-brown to brownish-gray in color.		
			5	96	BG			(2-6') Silt, clayey, dark yellowish-brown with dark yellowish-orange staining. Trace of organic material.		
			6	100	BG			Finely laminated and contains small iron-manganese nodules from 4-6'.		
10			7	100	BG		ML	(6-8') Silt, decreasing clay content and increasing iron-manganese nodule content. Yellowish-brown to light olive gray, moist.		
			8	100	BG			(8-18') Silt, slightly clayey yellowish-gray to light olive gray color, moist.		
15			9	100	BG			Increase in dark yellowish-orange staining, moisture content, and iron-manganese content from 10-14'.		
			10	92	BG			Stained dark yellowish-orange in color from 14-16'. Very moist from 14-15'.		
20			11	83	BG			Less staining from 16-18'. Very moist from 16' to 17' (water came up the borehole when auger was advanced).		
			12	100	BG			(18-19') Silt, slightly clayey, medium gray in color. Moist.		
			13	100	BG			(19-20') Silt, slightly clayey, yellowish-gray to light olive gray, moist.		
25			14	100	BG			(20-22') Silt, slightly clayey, medium light gray to light gray, stained moderate brown, moist.		
			15	100	BG		ML	(22-24') Silt, clayey, pale yellowish-brown to pale brown color, moist.	241.2	
							ML	(24-28') Silt (see descriptions below).		
								(24-26') Silt; medium gray to brownish-gray with patches of dark yellowish-orange material. Moist.		
							ML	(26-28') Silt; light olive gray to medium gray. Slightly moist.	237.2	
30								(28-33') Silt, sandy (see descriptions below).

Measurement of Hydraulic Conductivity

Client: EnSafe/Allen & Hoshall

Date of Report: 02/29/96

Project No.: E-3-157

Client's Project No.: 0106090000

Sample I.D.: 009S01DA18

Soil Description: Tan & Light Gray Silty Clay

Test Media: City of Memphis Water

	<u>Pre-Test</u>	<u>Post Test</u>
Wet Density (Lbs/ft ³)	122.1	120.5
Dry Density (Lbs/ft ³)	91.3	91.0
Moisture (% Dry Wt)	33.8	32.4
Porosity (n)	.43	.44
Degree of Saturation (%)	1.0	1.0
Specific Gravity (ASTM D-854)	2.59	---

Permeability

Temperature Correction, $R_t = 1.043$

- $K_1 = 9.0 \times 10^{-7}$ cm/sec
- $K_2 = 8.5 \times 10^{-7}$ cm/sec
- $K_3 = 9.4 \times 10^{-7}$ cm/sec
- $K_4 = 9.9 \times 10^{-7}$ cm/sec

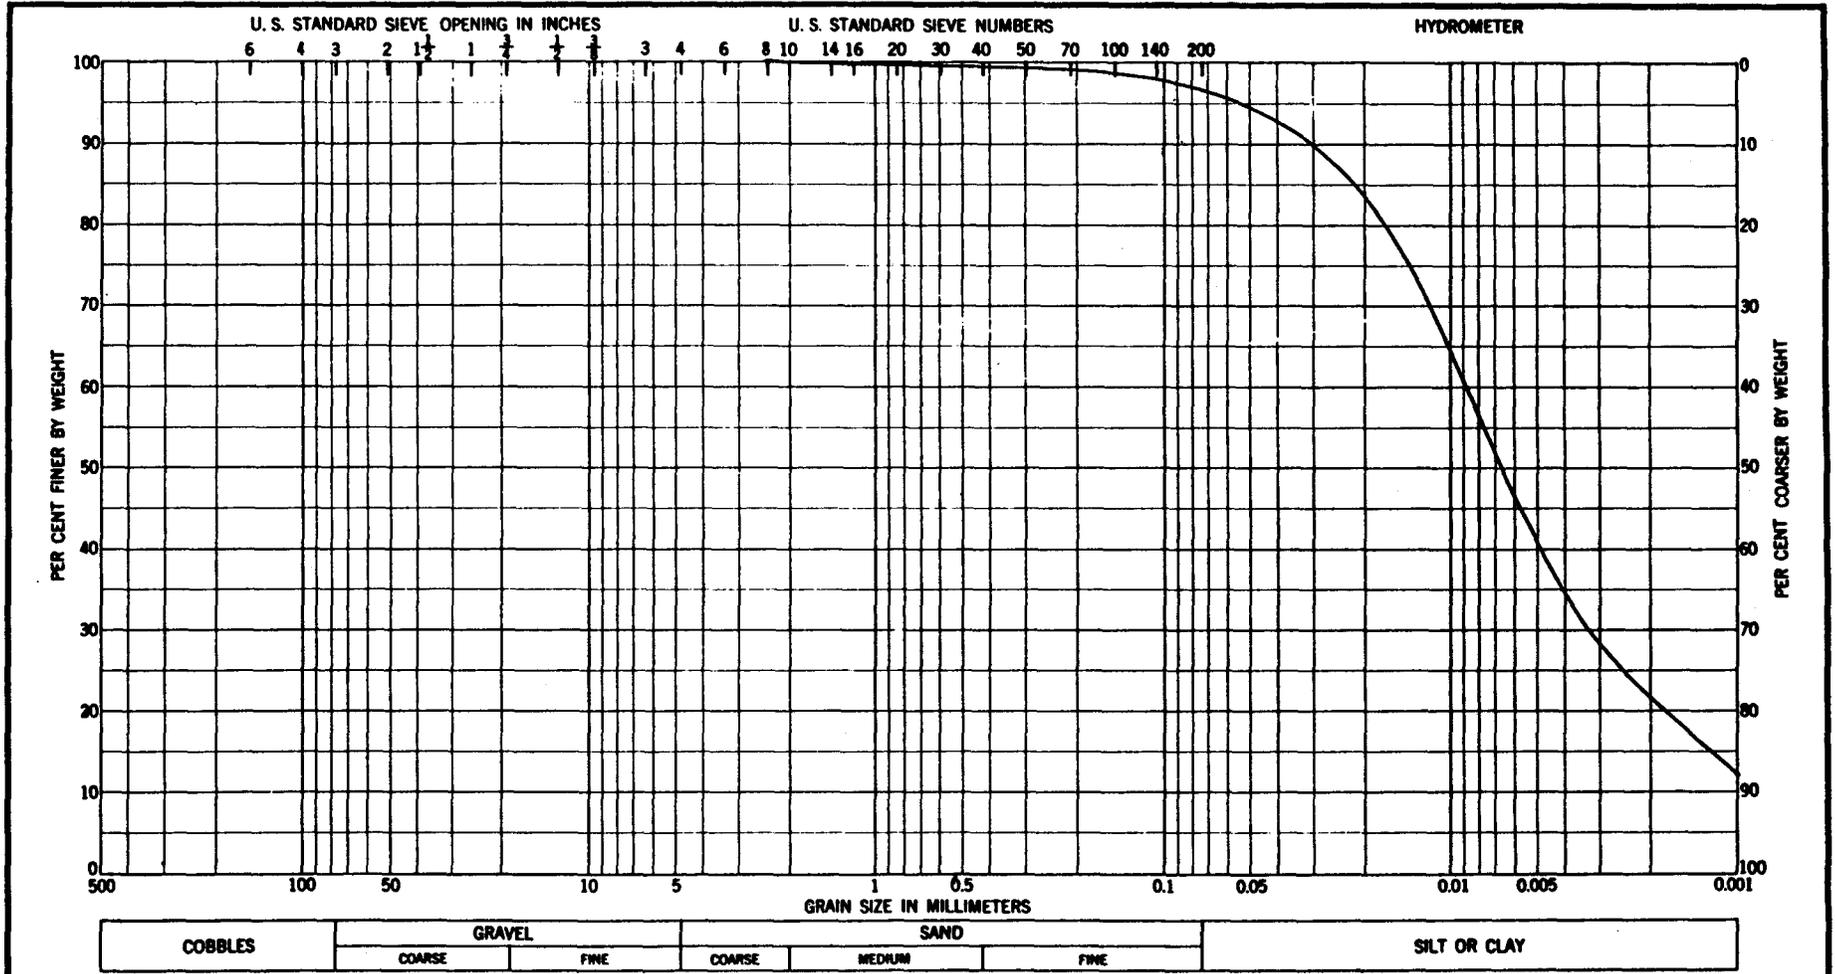

Coefficient of Permeability, $K_{20} = 9.6 \times 10^{-7}$ cm/sec

Tested in accordance with ASTM D-5084-90.

Lab No. P-96-011

MEMORANDUM

TO: Rob Williamson
NSA Memphis Public Works Environmental Division

Mark Taylor
SOUTHNAVFACENGCOM

FROM: Robert Smith *RS*
EnSafe/Allen & Hoshall

SUBJECT: Characterization of Investigation-Derived Waste from Assembly E
SWMUs: NSA Memphis RFI, Millington, Tennessee; CT0-106

DATE: October 14, 1996

Beginning in November 1995, EnSafe/Allen & Hoshall conducted a RCRA Facility Investigation at Naval Support Activity (NSA) Memphis. Investigation derived waste (IDW) was generated during the investigation.

The IDW consisted of two types of media: soil/formation material, and water. The water was generated from activities such as decontamination of soil and groundwater sampling equipment, development of groundwater monitoring wells, and purging of the monitoring wells prior to sampling. The water was contained in a 2,000 gallon polyethylene tank at Facility S-775. Each time the tank reached its capacity, a sample was collected by E/A&H for analysis by an offsite laboratory for waste characterization parameters. The analytical results from the IDW characterization were then submitted to the City of Millington's contracted engineer, Mr. James Cox of Fisher & Arnold Engineering for discharge approval. Upon receiving discharge approval from Mr. Cox, the contents of the tank were discharged to the sanitary sewer system via an onsite oil/water separator. The 2,000 gallon tank has been cycled a total of 13 times since the beginning of the Assembly E investigation.

The second media type, soil/formation material, was generated during drilling activities, which included drilling spoils and soil/mud generated during the decontamination of the drilling and sampling equipment. Formation material consisted of all subsurface material (sand, gravel, clay) brought to the surface during the drilling/sampling activities. All material generated was containerized in 168 DOT-approved, lined, 55-gallon drums, and were properly labeled and staged in the NSA Memphis IDW storage area (Facility N-1665), where they presently remain. During a recent inspection of the IDW containers, E/A&H found that all labels

placed on the drums have become illegible preventing the correlation of individual drums with specific boring locations. This IDW characterization has been conducted as a basis for disposal and is based the on the concentrations of compounds detected in the Assembly E soil borings.

CHARACTERIZATION

A total of 101 compounds were detected during the Assembly E RFI Investigation. Each compound has been characterized based on the U.S. Environmental Protection Agency (USEPA) Hazardous Waste Rules as outlined in Title 40 of the Code of Federal Regulations, Part 261 (40 CFR 261), and the guidelines set forth by Tennessee Department of Environment and Conservation (TDEC), Division of Solid Waste Management (DSWM).

Of the 101 compounds detected, the following six compounds were defined in 40 CFR 261.30 as being "F-listed" hazardous wastes. F-listed wastes, by definition, are compounds from specific sources, which have been listed due to their Hazard Code (i.e., Toxicity, Ignitability, Corrosivity). The criteria for the selection of these compounds, as well as the USEPA Region III Risk-Based Concentration (RBC) and pertinent ignitability data, is presented in Table 1:

Table 1
 NSA Memphis RFI; Assembly E IDW Characterization
 F-Listed Wastes

Compound	Hazardous Waste Code as defined in 40 CFR 261	Maximum Detected Concentration ($\mu\text{g}/\text{kg}$)	Residential RBC ($\mu\text{g}/\text{kg}$)	Flashpoint (ignitability) ($^{\circ}\text{C}/^{\circ}\text{F}$)	Selection Criteria as defined in 40 CFR 261
Trichloroethylene	F001	19.0	58,000	N/A	Toxicity
Methylene Chloride	F002	5.0	85,000	N/A	Toxicity
Tetrachloroethene	F002	23.0	12,000	N/A	Toxicity
4-methyl-2-pentanone (MIBK)	F003	170	N/A	17.8 $^{\circ}\text{C}/64^{\circ}\text{F}$	Ignitability
Acetone	F003	48000	7,800,000	0 $^{\circ}\text{C}/0^{\circ}\text{F}$	Ignitability
2-butanone (MEK)	F005	3600	47,000,000	-8.75 $^{\circ}\text{C}/16^{\circ}\text{F}$	Ignitability, Toxicity

Notes:

N/A = Data not available

According to 40 CFR 261.3(a)(2)(iii), "A solid waste, as defined in § 261.2, is a hazardous waste if....it is a mixture of a solid waste and a hazardous waste that is listed in Subpart D of this part solely because it exhibits one or more of the characteristics of hazardous waste identified in subpart C of this part, *unless the resultant mixture no longer exhibits any characteristics of hazardous waste identified in subpart C of this part.....*"

According to 40 CFR 261.30, the F001 and F002 wastes (trichloroethylene, methylene chloride, and tetrachloroethene) were listed due to their toxicity, and the F005 waste (MEK) was listed due to its toxicity and ignitability. Also, according to 40 CFR 261.30, the F003 (MIBK and Acetone)

wastes were listed due to their ignitability. Because of the low contaminant concentrations detected and the medium (i.e., soil) in which they are contained, soil found at the Assembly E SWMUs does not exhibit the ignitable characteristic. However, because toxicity cannot be physically defined as ignitability can, it would be difficult to prove that the soil/F001, soil/F002, and soil/F005 mixtures are not toxic.

The Land Disposal Restriction (LDR) Guide #5 provides the following discussion of the Contained-In Interpretation (USEPA Office of Solid Waste Management dated November 13, 1986). "The contained-in policy states that any mixture of a non-solid waste and a RCRA listed hazardous waste must be managed as a hazardous waste as long as the material contains (i.e., is above health based levels) the listed hazardous waste." The contained in policy was developed to address contaminated environmental media (i.e., soil, groundwater, surface water), as opposed to the mixture rule which governs mixtures of hazardous and solid wastes. E/A&H has previously confirmed that TDEC's DSWM concurs with and applies the USEPA contained-in policy using RBCs as health-based levels.

Characterization of the soil/formation material generated during the RFI will be based on the contained in policy. Past disposal of soil at NSA Memphis has also applied the contained-in policy in this situation (Memorandum, *Characterization of Investigation Derived Waste from Assembly A SWMUs*; CTO-094; June 6, 1995). A comparison of the soil boring data to the residential RBCs for soil (Table 1) shows that the maximum concentrations of the potentially listed hazardous wastes contained in the IDW do not exceed the health-based risk levels.

Petroleum Constituents

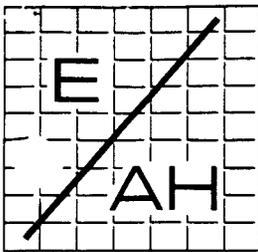

As part of the full scan analytical parameter list associated with the investigation, each sample collected was submitted for total petroleum hydrocarbon (TPH) analysis using the Tennessee-

modified USEPA methods 8015 for gasoline range organics (GRO) and diesel range organics (DRO). The maximum detected concentrations of TPH-GRO and TPH-DRO were 260 mg/kg and 650 mg/kg, respectively; however, the average detected concentrations of TPH-GRO and TPH-DRO were 7.5 mg/kg and 49.8 mg/kg, respectively; with 4% of the samples analyzed exceeding 100 mg/kg TPH. Because labels on the drums containing the IDW are illegible, individual sample results cannot be correlated to the representative IDW on a drum by drum basis. Therefore, all IDW must be characterized together as one unit; for this reason, the average of all detected results was used in the characterization process. Based on the low average concentration of petroleum constituents detected, and the infrequency of detections exceeding 100 mg/kg of TPH, the material would not meet the TDEC DSWM criteria for a petroleum contaminated soil of 100 mg/kg TPH.

NON-HAZARDOUS IDW DISPOSAL

Options for the disposal of the non-hazardous IDW include:

1. All soil and formation material can be spread or buried at an existing SWMU (e.g., Salvage Yard #2, SWMU 41) on property being retained by the Navy, preferably in a single, predetermined area to facilitate future locating and sampling of the material, if necessary. The spreading of this material at an existing SWMU would eliminate the potential for creating a future SWMU and material handling activities should blend the IDW, creating a more homogeneous mixture, which would be more representative of the average concentrations discussed previously.
2. All soil can be sent to a TDEC-approved, non-hazardous landfill.

Memorandum

Date: January 24, 1997
To: NSA Memphis, BRAC Cleanup Team
From: Robert Smith, E/A&H/SG
Re: Assembly E IDW Drum Screening Results

E/A&H has recently completed the drum screening activities associated with the NSA Memphis Assembly E investigation derived waste (IDW). The drum screening, conducted at the request of the BCT, was in response to the *Characterization of Investigation-Derived Waste from Assembly E SWMUs* memorandum (E/A&H, October 14, 1996) which stated that 4% of the samples collected during the Assembly E RFI contained petroleum hydrocarbon concentrations exceeding 100 mg/kg.

The screening activities were conducted following the procedures outlined in the *Drum Screening Procedures, Assembly E IDW* memorandum (E/A&H, December 9, 1996) presented to the BCT, with one procedural change made at the request of Mr. Jim Morrison (Tennessee Department of Environment and Conservation [TDEC]). In addition to collecting headspace data from each drum, a sample was also collected from each drum and placed in an air tight bag (i.e., zip-lock), and the contents of the bag were subsequently screened using a flame ionization detector (FID).

At the request of TDEC, their office was notified prior to beginning any screening activities; however, due to technical difficulties associated with the instruments (i.e., PID, FID), no work was performed while TDEC was on site.

The data, presented in the attached table and associated graph, indicate that 6 out of the 160 (3.75%) drums screened exhibited elevated organic vapor concentrations in relation to the rest of the drums. Due to varying factors associated with organic vapor readings and containerized soil (i.e., painted surfaces on the interior of the drum, moisture, etc.), the organic vapor levels detected may or may not be indicative of the petroleum concentration of the drum contents.

The available disposal options for the Assembly E IDW include onsite disposal (identical to the Assembly A IDW), however, the petroleum levels in the soil may need to be confirmed by collecting samples of the material contained in the 6 drums exhibiting elevated headspace readings. If the BCT decides the data is needed, composite samples will be collected from each drum using a stainless steel hand auger to allow the samplers to obtain material from 3 points within the material contained in each drum. These composite samples, a total of 6, would be submitted for total petroleum hydrocarbon analysis by EPA Method 418.1.

Should the analytical data indicate that the petroleum levels of any of the drums exceed the current TDEC definition of a petroleum contaminated soil (presently 100 ppm TPH), that drum will be segregated for disposal under the TDEC Special Waste Policy. The remaining soil may be spread onsite, at a location agreed upon by the NSA Memphis Public Works Office and the BCT.

**Technical Memorandum —
General Human Health Risk Assessment**

TECHNICAL MEMORANDUM

TO: Mark Taylor/David Porter, SOUTHDIV
Tonya Barker/Rob Williamson, NSA Memphis
Brian Donaldson, USEPA
Jim Morrison, TDEC
Jack Carmichael, USGS
Brenda Duggar, MSCHD
E/A&H Project Team

FROM: Brian Mulhearn, E/A&H

DATE: February 4, 1997

RE: **Revision 1 General Human Health Risk Assessment (HHRA) Approach
for NSA Memphis**

This memorandum discusses the general HHRA approach for NSA Memphis and incorporates USEPA's suggestions received during the January 28, 1997 Base Realignment and Closure (BRAC) Cleanup Team meeting. This text will not be reproduced in subsequent HHRAs with the exception of the final report, where the text will be included as an appendix. Initially, HHRAs will include only site-specific information and will reference this memorandum, reducing the bulk necessary to present site-specific risk information to risk managers. Deviations from these general methods will be justified and discussed in site-specific HHRAs.

1 BASELINE RISK ASSESSMENT

1.1 Introduction

A baseline risk assessment (BRA) establishes a baseline of risk to facilitate risk management decisions. Risk is the estimated potential for toxic effects on actual or hypothetical human or ecological receptors, while baseline risk refers to risk arising from exposures to chemicals assuming site conditions remain unchanged. BRAs are used by risk managers to decide if remedial actions are necessary and to determine the extent of remediation necessary to reduce the risk to acceptable levels. Generally, a BRA is divided into two sections, one assessing human health risk, and a second addressing ecological risk. This section addresses generally applied HHRA methods, while ecological risk assessment methods will be addressed in the site-specific assessments. Data management and analysis methods which will be used to reach the conclusions of site-specific HHRA are discussed below. The following sections describe the methods, procedures, considerations, toxicological information, and related uncertainties possibly affecting HHRA at NSA Memphis.

1.2 Background

The site background will be summarized in this section of the site-specific HHRA.

2 General Guidance

HHRA will generally be prepared in accordance with the guidelines set forth in the following documents, although some may not apply to every site:

- *Provisional Guidance for Quantitative Risk Assessment of PAHs*, U.S. Environmental Protection Agency, ECAO-CIN-842, EPA/600/BP92/001C, July 1993.
- *Risk Assessment Guidance for Superfund (RAGS), Volume I – Human Health Evaluation Manual, Part A*, U.S. Environmental Protection Agency/Office of Emergency and Remedial Response (OERR), EPA/540/1-89/002, December 1989 (Interim).

- *RAGS, Volume I – Human Health Evaluation Manual, (Part B, Development of Risk-Based Preliminary Remediation Goals), USEPA/OERR, EPA/540/R92/003, December 1991 (Interim).*
- *RAGS, Volume I – Human Health Evaluation Manual, Supplemental Guidance – Standard Default Exposure Factors – Interim Final, EPA/OERR, Office of Solid Waste and Emergency Response (OSWER) Directive: 9285.6-03, March 25, 1991. (RAGS Supplement).*
- *RAGS, Volume I – Human Health Evaluation Manual, Supplemental Guidance-Dermal Risk Assessment – Interim Guidance, EPA/OERR, August 18, 1992. (Supplemental Dermal Guidance).*
- *Supplemental Guidance to RAGS: Region IV Bulletin, Development of Health-Based Preliminary Remediation Goals, Remedial Goal Options (RGO) and Remediation Levels (Supplemental RGO Guidance).*
- *Supplemental Guidance to RAGS: Region IV Bulletin, Provisional Guidance of Quantitative Risk Assessment of PAHs (EPA Document EPA/600/R-93-089 July 1993).*
- *Supplemental Guidance to RAGS: Calculating the Concentration Term, May 1992.*
- *USEPA Region III Selecting Exposure Routes and Contaminants of Concern by Risk-Based Table, March 18, 1994, (RBC Screening Tables).*
- *USEPA Region III Risk-Based Concentration Table, January 1995, and subsequent versions (USEPA 1995).*

2.1 Objectives

The objectives of the BRA will be to:

- Characterize the source media and determine the chemicals of potential concern (COPCs) for affected environmental media.
- Identify potential receptors and quantify their potential exposures under current and future conditions for all affected environmental media.
- Qualitatively and quantitatively evaluate the adverse effects associated with the site-specific COPCs in each medium.
- Characterize the baseline carcinogenic and noncarcinogenic risks associated with exposure to environmental media at the site(s) under current and future land use conditions.
- Evaluate the uncertainties related to exposure predictions, toxicological data, and resulting carcinogenic risk and noncarcinogenic hazard estimations.
- Establish Remedial Goal Options (RGOs) for chemicals of concern (COC) in each environmental medium based on risk/hazard to facilitate risk management decision-making.

The value of the risk assessment as a basis for making remedial decisions and determining whether detected site concentrations have the potential for toxic effects or increased cancer incidences depends upon adequately characterizing chemical contamination. Variables considered in characterizing the study area and its associated risk will include the amount, type, and location of sources; the pathways of exposure (media type and migration routes); and the type, sensitivities, exposure duration, and dynamics of the exposed populations (receptors). Sampling activities

typically consist of collecting surface (0 to 1-foot interval) and subsurface soil samples, and groundwater samples from monitoring wells installed in various water-bearing zones.

2.2 Organization

A human health risk assessment, as defined by RAGS Part A, includes the following steps:

- *Site characterization:* evaluation of data regarding site geography, geology, hydrogeology, climate, and demographics.
- *Data collection:* analysis of environmental media samples, including background/reference samples.
- *Data evaluation:* statistical analysis of analytical data to identify the nature and extent of contamination and to establish a preliminary list of COPCs based on risk-based and background screening. This list will subsequently be refined to identify COCs.
- *Exposure assessment:* identification of potential receptors under current and predicted conditions and potential exposure pathways, and calculation/quantitation of exposure point concentrations and chemical intakes.
- *Toxicity assessment:* qualitative evaluation of the adverse effects of the COPCs, and quantitative estimate of the relationship between exposure and severity or probability of effect.
- *Risk characterization:* combination of the output of the exposure and the toxicity assessments to quantify the total noncancer and cancer risk to the hypothetical receptors.

- *Uncertainty*: discussion and evaluation of the areas of recognized uncertainty in human health risk assessments in addition to medium - and exposure pathway-specific influences.
- *Risk/hazard summary*: presentation and discussion of the results of the quantification of exposure (risk and hazard) for the potential receptors and their exposure pathways identified under the current and future conditions.
- *RGOs*: computation of exposure concentrations corresponding to risk projections within the USEPA target risk range of $1E-6$ to $1E-4$ for carcinogenic COCs and hazard quotient goals of 0.1, 1, and 3 for noncarcinogenic COCs.

3 Site Characterization

When performing a HHRA, environmental media data are compiled to determine potential site-related chemicals and exposures as outlined in RAGS Part A. The steps identifying COPCs are discussed below.

3.1 Data Sources

The number of samples collected from each medium will be detailed in this section of the site-specific HHRAs, and tables will show which sample designations will be included and how data are grouped (when applicable). In addition, the analytical methods, the name of the analyzing laboratory, and data quality objectives will be referenced at this point in the HHRA.

3.2 Data Validation

Data validation is an after-the-fact, independent, systematic process of evaluating data and comparing them to established criteria to confirm they are of the technical quality necessary to support the decisions made in the RFI process. Parameters specific to the data are reviewed to determine whether they meet the stipulated DQOs. The quality objectives address five principal

parameters: precision, accuracy, completeness, comparability, and representativeness. To verify that these objectives are met, field measurements, sampling and handling procedures, laboratory analysis and reporting, and nonconformances and discrepancies in the data are examined to determine compliance with appropriate and applicable procedures.

Data for NSA Memphis will be validated in accordance with the methods outlined in the *Comprehensive RFI Work Plan (E/A&H, 1994b)*. The data validation report will be referenced in this section of the HHRA.

3.3 Management of Site-Related Data

All environmental sampling data will be evaluated for suitability for use in the quantitative BRA. Data obtained via the following methods will be considered inappropriate:

- Analytical methods that are not specific for a particular chemical, such as total organic carbon, total organic halogen, or TPH (design parameter samples).
- Field screening instruments including total organic vapor monitoring units and organic vapor analyzers.

Additional data excluded will be detailed in the site-specific HHRAs.

Limitations of analytical results will be addressed in HHRAs by including estimated concentration values for reported nondetects. A nondetect indicates that the analyte was not detected above the practical quantitation limit of the sample ("U" qualified results), which is determined by the analytical method, the instrument used, and possible matrix interferences. However, a nondetected analyte could exist at a concentration between zero and the quantitation limit. For this reason, one-half the "U" value could serve as an unbiased estimate of the nondetect. Because the

estimated values of "J" qualified hits are frequently much lower than the sample quantitation limits of "U" qualified nondetects for organic compounds, one-half of each "U" value will be compared to one-half of the lowest hit (normally "J" qualified) at the same site. The lesser of these two values will be used as the best estimate of the concentration potentially present below the sample quantitation limit, and will be inserted into the adjusted dataset. For inorganic chemicals, the rule is simpler: One-half of each "U" value will be used to represent the concentration of the corresponding sample when compiling the adjusted dataset. If two nondetects are reported for any one location (a result of QA/QC samples), one-half the lesser of the "U" values will be compared to the lowest hit at the site (for organics, as above) or applied directly (for inorganics) to estimate a concentration value to be used in the NSA Memphis risk calculations. If a parameter is not detected at a site, neither data management method will be applied, and the parameter will not be considered in screening or formal assessment.

Once the dataset is complete, statistical methods will be used to evaluate the analytical results to (1) identify COPCs and (2) establish exposure point concentrations (EPCs) at potential receptor locations. The statistical methods used in data evaluation are discussed below. The rationale used to develop this methodology and the statistical techniques is based on the following sources:

- RAGS Part A
- *Supplemental Guidance to RAGS: Calculating the Concentration Term*, May 1992
- *Statistical Methods for Environmental Pollution Monitoring* (Gilbert, 1987)

Microsoft Fox Pro and Borland¹ Quattro Pro will typically be used for data management and statistical calculations. For each set of data used to describe the concentration of chemicals in a contaminated area, the following information will be tabulated in accordance with RAGS:

¹ *References to specific software products are not to be construed as an endorsement by the U.S. Navy or E/A&H.*

frequency of detection, range of quantitation limits, range of detected values, and average of detected concentrations. For datasets of 10 or more, the upper confidence limit (UCL) on the mean of log-transformed values of the concentration will be presented. In accordance with RAGS, the lesser of either the maximum concentration detected or the UCL will be used to quantify potential exposure, as detailed in Section 4, Exposure Assessment.

3.4 Selection of COPCs

The substances detected (chemicals present in site samples, or CPSSs) will be screened to develop a list or group of COPCs. COPCs are, therefore, chemicals selected by comparison to screening concentrations, intrinsic toxicological properties, persistence, fate and transport characteristics, and cross-media transport potential. The nature and general extent of CPSSs will be referenced in this section of the site-specific HHRA. To reduce the list of CPSSs and focus the risk assessment on COPCs, the following two comparisons will be performed.

3.4.1 Comparison of Site-Related Data to Risk-Based Screening Concentrations

The maximum concentrations of CPSSs detected during sampling will be compared to risk-based screening values. These values will be obtained from *Risk Based Screening Concentrations*, USEPA Region III, January through June, 1996 (and subsequent versions). As stated in the EPA Region III document, a risk goal of 1E-6 will be used to calculate screening concentrations for carcinogens. RBCs will be adjusted to reflect a target HQ of 0.1 for noncarcinogens, in accordance with USEPA Region IV *Supplemental Guidance to RAGS Bulletin 1* (USEPA, November 1995). Groundwater results will be compared to tap water screening values, and reported soil concentrations will be compared to residential soil screening values. CPSSs with maximum detected concentrations exceeding their corresponding concentrations, goals, levels, and/or standards will be evaluated further and compared to reference background concentrations. In addition, surrogate screening values based on toxicological similarities will be used if no screening value are available in USEPA's table, and surrogate screening values will be noted where applied.

The maximum concentration reported for each carcinogenic polycyclic aromatic hydrocarbon (PAH) will be compared to its corresponding screening value. In addition, all carcinogenic PAH concentrations reported at that location will be converted to the benzo(a)pyrene equivalent concentration (BEQ), which will be compared to the screening value for benzo(a)pyrene. PAH conversions will be performed using current Toxic Equivalency Factors (TEFs) for PAHs in accordance with USEPA Region IV *Supplemental Guidance to RAGS Bulletin 2* (USEPA, November 1995).

3.4.2 Comparison of Site-Related Data to Background Concentrations

Background data for NSA Memphis will be referenced in this section, or background reference concentrations from E/A&H's August 27, 1996 *Reference Concentrations* technical memorandum will be used. Following comparison to risk- and hazard-based screening values, CPSSs whose maximum detected concentrations exceeded corresponding background reference concentrations will be formally assessed in the HHRA, unless otherwise noted.

The maximum reported concentration of a CPSS will be compared to its reference background concentration (when applicable). This comparison helps account for naturally occurring elements, such as beryllium, manganese, and arsenic. Thus, risk and/or hazard associated with naturally occurring elements are not addressed where their concentrations are similar to corresponding background.

In the HHRA, if the maximum concentration of a CPSS is determined to be less than either two-times mean background or the risk-based screening values, then the CPSS will not be considered further unless deemed appropriate based on chemical-specific characteristics (e.g., degradation product with greater toxicity).

3.4.3 Elimination of Essential Elements: Calcium, Iron, Magnesium, Potassium, and Sodium

In accordance with RAGS Part A, essential elements that are potentially toxic only at extremely high concentrations may be eliminated as COPCs in a risk assessment. Specifically, an essential nutrient may be screened out if it is present at concentrations that are not associated with adverse health effects. Based on RAGS, the lack of risk-related data, and USEPA Region IV's recommendations, the following essential nutrients will not be included in HHRAs: calcium, iron, magnesium, potassium, and sodium.

Risk information usually obtained from the Integrated Risk Information System (IRIS) or Health Effects Assessment Summary Tables (HEAST) is necessary to calculate risk and hazard estimates (and risk-based screening values). This information is based on toxicological and epidemiological data which are critiqued and approved by the scientific and regulatory community (i.e., listed in IRIS and/or HEAST). Risk information (or surrogate risk information) is not always available for all CPSSs, so their risk and/or hazard will not be calculated. The results of the screening process will be tabulated in the HHRA. No risk-based screening values are available for TPH and chemical-specific analyses were performed on site samples, so exposure will not be quantified for this group of compounds. The most toxic TPH constituents would generally be included in the chemical-specific analyses.

3.4.4 Summary of COPCs

The results of the screening evaluations will be tabulated on a medium-specific basis in the site-specific HHRAs.

3.5 Estimation of Risk and Hazard

COPCs will be identified, and exposure will be estimated for these compounds. Risk/hazard will be subsequently calculated based on exposure estimates, then exposure scenarios (e.g., soil

exposure during commercial land use) exceeding USEPA acceptable limits will be identified. An exposure scenario of concern will be identified as a scenario with incremental excess lifetime cancer risk (ILCR) estimated greater than $1E-4$ or a hazard index (HI) estimated greater than 1. In the next step, COPCs exceeding $1E-6$ ILCR or a HQ greater than 0.1 in a scenario of concern are retained as COCs. Section 5, Toxicity Assessment, discusses cancer risk thresholds and noncancer toxicity in detail.

4 Exposure Assessment

This section of the HHRAs will determine the magnitude of contact that a potential receptor may have with site-related COPCs. Exposure assessment involves four stages:

- Characterizing the physical setting and land use of the site.
- Identifying COPC release and migration pathway(s).
- Identifying the potential receptors, under various land use or site condition scenarios, and the pathways through which they might be exposed.
- Quantifying the intake rates, or contact rates, of COPCs.

4.1 Exposure Setting and Land Use

The site setting and land use will be detailed or referenced in this section of the site-specific HHRAs. This information is used to develop appropriate exposure estimates for different land use assumptions. If the future use of the area in question is known, this information will be used to define exposure assumptions used when calculating risk (e.g., sites known to be commercially zoned will not be assessed for residential land use). Future land use will be specified with as much accuracy as possible in site-specific HHRAs, particularly for property being transferred from the Navy to the City of Millington.

4.2 Potentially Exposed Populations

This section will describe who may be exposed to contaminants in environmental media. The populations typically addressed will be one or a combination of the following: current site workers, hypothetical current site trespassers, as well as hypothetical future site residents. Because current site workers at most sites within NSA Memphis would be expected to have limited contact with contaminated media at most sites, worker-related exposure may be addressed exclusively for maximally exposed site workers, assuming the future worker scenario would be protective of both current and future site workers. Specifics will be discussed in this section of the site-specific HHRAs.

4.3 Exposure Pathways

This section will summarize how potential human receptors may be exposed to site media. In general, soil matrix-related pathways will include incidental ingestion and dermal contact. Ingestion and inhalation of volatilized contaminants will be typical groundwater exposure pathways. The hypothetical future scenarios will assume continuous, uniform exposure to current surface soil conditions and the use of site groundwater as a potable water source, unless otherwise noted in the site-specific HHRA. A table in the site-specific HHRA will justify and summarize exposure pathways and potential human receptors.

4.4 Exposure Point Concentrations

The EPC is the estimated concentration of a contaminant in an exposure medium that will be contacted by a real or hypothetical receptor. Determining the exposure point concentration depends on factors such as:

- Availability of data
- Amount of data available to perform statistical analysis
- Reference concentrations not attributed to site impacts
- Location of the potential receptor

USEPA Region IV guidance calls for assuming lognormal distributions for environmental data and the calculation of 95% UCL on the mean for use in exposure quantification. Applying the UCL is generally inappropriate with less than 10 samples. Therefore, the maximum concentrations detected will be used for all datasets with less than 10 samples. In general, outliers have been included when calculating the UCL because high values seldom appear as outliers for a lognormal distribution. Including outliers increases the overall uncertainty of the calculated risks and conservatively biases exposure estimates.

For sample sets of 10 and greater, the UCL will be calculated for a lognormal distribution as follows:

$$\text{UCL} = e^{\left(\bar{a} + 0.5s_a^2 + \frac{H_{0.95} \times s_a}{\sqrt{n-1}} \right)}$$

where:

- \bar{a} = $\Sigma a/n$ = sample arithmetic mean of the log-transformed data, $a = \ln(x)$
- s_a = sample standard deviation of the log-transformed data
- n = number of samples in the data set
- $H_{0.95}$ = value for computing the one-sided upper 95% confidence limit on the lognormal mean from standard statistical tables (Gilbert, 1987)

EPCs and UCLs will be summarized and tabulated when applicable in the site-specific HHRA.

4.5 Quantification of Exposure

This section describes the models, equations, and intake model variables used to quantify doses or intakes of the COPCs for the surface soil and groundwater exposure pathways. The models are

designed to estimate route- and medium-specific factors, which are multiplied by the EPC to estimate chronic daily doses. The intake model variables generally reflect 50th or 95th percentile values which, when applied to the EPC, ensure that the estimated intakes represent the reasonable maximum exposure (RME, which is considered 95th percentile). Formulae are derived from RAGS, Part A unless otherwise indicated. Table 1 lists intake model variables used to compute chronic daily intake (CDI) for potential receptors exposed to surface soil and/or groundwater contaminants.

Because NSA Memphis is part of BRAC, future site use cannot be determined with any certainty. Therefore, the conservative assumptions will be used to account for any reasonable future use. Current reuse plans will be referenced and discussed in the site-specific HHRAs. NSA Memphis media analytical results and exposure methods have been formatted to allow exposure estimates to be fine-tuned based on actual conditions as base reuse plans materialize, and this information will be used on a site-specific basis, if known.

In accordance with USEPA's recommendations, the adult and child intake variables will be combined to estimate exposure to carcinogens. This factor is referred to as the lifetime weighted average, or LWA. The LWA considers the difference in daily ingestion rates for soil and drinking water, body weights, and exposure durations for children (ages 1 to 6) and adults (ages 7 to 31). The exposure frequency is assumed to be identical for the adult and child exposure groups, and an example is shown after the equations are presented below.

Before quantifying soil exposure, it will first be necessary to derive the appropriate fraction ingested (or contacted) (FI/FC) from contaminated area factors for each applicable COPC. These factors will be derived by evaluating the spatial distribution of COPCs. The FI/FC will be computed by estimating the maximum area affected and dividing it by the total exposure unit area. These computations will be performed conservatively to account for uncertainty associated with contaminant distributions.

Table 1
Parameters Used to Estimate CDI

Pathway Parameters	Resident Adult	Resident Child	Adult Worker	Trespassing Child (age 7-16)	Units
Surface Soil Ingestion and Dermal Contact					
Ingestion Rate (soil)	100 ^a	200 ^a	50 ^a	100 ^a	mg/day
Ingestion Rate (water)	2	1	1	NA	L/day
Exposure Frequency	350 ^b	350 ^b	250 ^b	52 ^f	days/year
Exposure Duration	24 ^c	6 ^c	25 ^c	10 ^a	years
Dermal Contact Area	4,100 ^a	2,900 ^a	4,100 ^a	4,100 ^a	cm ²
Skin Adherence Factor	1	1	1	1	mg/cm ²
Absorption Factor	0.01 (organics) 0.001 (inorganics)	0.01 (organics) 0.001 (inorganics)	0.01 (organics) 0.001 (inorganics)	0.01 (organics) 0.001 (inorganics)	unitless
Oral Absorption Efficiency	0.8 (VOCs) 0.5 (other organic compounds) 0.2 (inorganics)	unitless			
Conversion Factor	1E-6	1E-6	1E-6	1E-6	kg/mg
Body Weight	70 ^a	15 ^a	70 ^a	45 ^a	kg
Averaging Time, Noncancer	8,760 ^d	2,190 ^d	9,125 ^d	3,650 ^d	days
Averaging Time, Cancer	25,550 ^e	25,550 ^e	25,550 ^e	25,550 ^e	days

Notes:

- a — USEPA (1989a) *Risk Assessment Guidance for Superfund Vol. 1, Human Health Evaluation Manual (Part A)*.
- b — USEPA (1991b) *Risk Assessment Guidance for Superfund Vol. 1: Human Health Evaluation Manual Supplemental Guidance, Standard Default Exposure Factors, Interim Final*, OSWER Directive: 9285.6-03.EPA/600/8-89/043.
- c — USEPA (1991a), *Risk Assessment Guidance for Superfund: Vol. 1 – Human Health Evaluation Manual (Part B, Development of Risk-Based Preliminary Remediation Goals)*, OSWER Directive 9285.7-01B.
- d — Calculated as the product of ED (years) x 365 days/year.
- e — Calculated as the product of 70 years (assumed lifetime) x 365 days per year.
- f — Assuming one day per week exposure.
- g — Assuming trespassing occurs during the 10-year adolescent/teenage period.
- NA — Not applicable.

The FI/FC factors modify the concentrations to more closely approximate site-wide exposure conditions for a given exposure unit area. When the UCL is used as EPC, no FI/FC adjustments will be made. In addition, CPSSs not eliminated from the HHRA based on the screening comparisons described in Section 3.4 may be eliminated as a COPC because the UCL concentration does not exceed the corresponding background concentration or RBC. This will be discussed on a site-specific basis.

4.5.1 Surface Soil Pathway Exposure

Ingestion of COPCs in Surface Soil

Except CDI for a site resident's exposure to carcinogens, the following equation is used to estimate the ingestion of COPCs in soil:

$$CDI_s = (EPC_s)(IR)(EF)(ED)(F)(FI)/(BW)(AT)$$

where:

- CDI_s = ingested dose (mg/kg-day)
- EPC_s = exposure point concentration of contaminant in soil (mg/kg)
- IR = ingestion rate (milligrams per day [mg/day])
- EF = exposure frequency (days/year)
- ED = exposure duration (years)
- F = conversion factor (1E-6 kg/mg)
- FI = fraction ingested from contaminated source (unitless)
- BW = body weight (kg)
- AT = averaging time (days)

The LWA is used to calculate carcinogenic CDI for site residents. An example of the LWA calculation is shown below for the soil ingestion pathway, and LWAs are similarly calculated for subsequent equations.

$$LWA = [(IR_s \times ED_s)/BW_s] + [(IR_c \times ED_c)/BW_c]$$

where:

- LWA = lifetime weighted average
- IR = ingestion rate (milligrams per day [mg/day])
- ED = exposure duration (years)
- BW = body weight (kg)

a = adult

c = child

Consequently, CDI for carcinogens would be calculated as follows for site residents:

$$CDI_s = (EPC_s)(EF)(LWA)(F)(FI)/(AT)$$

where:

CDI_s = ingested dose (mg/kg-day)

EPC_s = exposure point concentration of contaminant in soil (mg/kg)

EF = exposure frequency (days/year)

F = conversion factor (1E-6 kg/mg)

FI = fraction ingested from contaminated source (unitless)

AT = averaging time (days)

LWA = lifetime weighted average

Dermal Contact with COPCs in Surface Soil

The following equation is used to estimate intake due to dermal contact with COPCs in soil:

$$CDI_{sd} = (EPC_s)(CF)(EF)(ED)(F)(FC)(ABS)(AF)/(BW)(AT)$$

where:

CDI_{sd} = dermal dose (mg/kg-day)

EPC_s = exposure point concentration of contaminant in soil (mg/kg)

CF = contact factor (cm²)

EF = exposure frequency (days/year)

ED = exposure duration (years)

F = conversion factor (1E-6 kg/mg)

FC = fraction contacted from contaminated source (unitless)

ABS = absorption factor (unitless value, specific to organic versus inorganic compounds)

- AF = adherence factor (milligrams per square centimeter [mg/cm²])
BW = body weight (kg)
AT = averaging time (days)

4.5.2 Groundwater Pathway Exposure

Ingestion and Inhalation of COPCs in Groundwater

The following equation is used to estimate the ingestion and/or inhalation of COPCs in groundwater:

$$CDI_w = (EPC_w)(IR)(EF)(ED)(FI)/(BW)(AT)$$

where:

- CDI_w = ingested/inhaled dose (mg/kg-day)
EPC_w = exposure point concentration of contaminant in water (milligrams per liter [mg/L])
IR = ingestion rate (L/day)
EF = exposure frequency (days/year)
ED = exposure duration (years)
FI = fraction ingested from contaminated source (unitless)
BW = body weight (kg)
AT = averaging time (days)

HHRAs are comprised of many tables, and intake tables serve only as an intermediate check when reviewing the document. The CDI equations above can be solved assuming a concentration of 1, and the result can be used as a universal multiplier. Multipliers were developed for each typical land use scenario and are shown in Table 2. Consequently, a significant number of the tables in HHRAs can be eliminated. An example of the abbreviated CDI method is shown below:

$$CDI = (EPC)(M)$$

where:

CDI = chronic daily intake (mg/kg-day)
EPC = exposure point concentration (mg/kg or mg/L)
M = multiplier specific to the exposure scenario, land use, and potential receptor selected

Table 2
Multipliers^a Used to Estimate Chronic Daily Intake

Exposure Scenario	Exposure Type	Soil		Groundwater
		Ingestion	Dermal Contact	Ingestion
		All Chemicals	Organics ^b	All Chemicals ^c
<i>Resident</i>	Noncarcinogens (adult)	1.37E-6	5.62E-7	2.74E-2
	Noncarcinogens (child)	1.28E-5	1.85E-6	6.39E-2
	Carcinogens (LWA)	1.57E-6	3.51E-7	1.49E-2
<i>Trespasser</i> (age 7-16)	Noncarcinogens	3.17E-7	1.30E-7	NA
	Carcinogens	4.52E-8	1.85E-8	NA
<i>Site Worker</i>	Noncarcinogens	4.89E-7	4.01E-7	9.78E-3
	Carcinogens	1.75E-7	1.43E-7	3.49E-3

Notes:

- NA — Not applicable
- LWA — Lifetime weighted average
- ^a — The product of the multiplier and the exposure point concentration equals the chronic daily intake for a given chemical assuming a reasonable maximal exposure scenario.
- ^b — The multiplier for inorganics is multiplied by a factor of 0.1 to account for the dermal absorption factor of 0.001 for inorganics; the multiplier for organic compounds includes the 0.01 factor.
- ^c — The ingestion intake is also used to address inhalation risk in accordance with USEPA's Supplemental Guidance To RAGS Bulletin 3; ingestion risk is approximately equal to risk posed by dermal and inhalation exposure while showering, and this is applied to volatile organic compounds only.

Because multipliers can be reviewed separately, CDI will be incorporated into the risk and hazard equations and *will not be presented* in separate tables.

5 Toxicity Assessment

5.1 Carcinogenicity and Noncancer Effects

USEPA has established a classification system for rating the potential carcinogenicity of environmental contaminants based on the weight of scientific evidence. The cancer classes are described below. Cancer weight-of-evidence class "A" (human carcinogens) means that human toxicological data have shown a proven correlation between exposure and the onset of cancer (in varying forms). The "B1" classification indicates some human exposure studies have implicated the compound as a probable carcinogen. Weight-of-evidence class "B2" indicates a possible human carcinogen based on confirmatory carcinogenic laboratory animal data. Weight-of-evidence class "C" identifies possible human carcinogens, and class "D" indicates a compound not classifiable with respect to its carcinogenic potential. A class "A" compound posing risk higher than USEPA's acceptable risk range has more weight than would a class "C" compound. There is more uncertainty in the lower classifications, so the weight-of-evidence should be used by risk managers when making risk management decisions based on cancer risk.

USEPA has established slope factors (SF) for carcinogenic compounds. The SF is defined as a "plausible upper-bound estimate of the probability of a response (cancer) per unit intake of a chemical over a lifetime" (RAGS, Part A). Upper-bound estimates are more likely to overestimate cancer potential.

In addition to potential carcinogenic effects, most substances also can produce other toxic responses at doses greater than experimentally derived threshold concentrations. USEPA has derived reference dose (RfD) values for these substances. A chronic RfD is defined as, "an estimate (with uncertainty spanning perhaps an order of magnitude or greater) of a daily exposure

concentration for the human population, including sensitive subpopulations, that is likely to be without an appreciable risk of deleterious effects during a lifetime." These toxicological values are used in risk formulae to assess the upper-bound level of cancer risk and noncancer hazard associated with exposure to a given chemical concentration.

For carcinogens, the potential risk posed by a chemical is computed by multiplying the CDI (as mg/kg-day) by the SF (in reciprocal mg/kg-day). The HQ (for noncarcinogens) is computed by dividing the CDI by the RfD. USEPA has set standard limits (or points of departure) for carcinogens and noncarcinogens to evaluate whether significant risk is posed by a chemical (or combination of chemicals). For carcinogens, the point-of-departure range is 1E-6, with a generally accepted range of 1E-6 to 1E-4. These risk values correlate with one in 10,000 (1E-4) and one in 1 million (1E-6) excess cancer incidence resulting from exposure to toxic compounds from outside the body.

For noncarcinogens, other toxic effects are generally considered possible if the HQ (or sum of HQs for a pathway-hazard index) exceeds the threshold value of 1. Although both cancer risk and noncancer hazard are generally additive only if the target organ is common to multiple chemicals, a most conservative estimate of each may be obtained by summing the individual risks or hazards, regardless of target organ. Site-specific HHRAs for NSA Memphis will take the universal summation approach for each class of toxicant. Details regarding the risk formulae applied to site data are provided in Section 6, Risk Characterization.

Critical studies used in establishing toxicity classifications by USEPA are shown in the IRIS database, which is the primary source for information necessary to estimate risk. HEAST, Fiscal Year 1995 is the secondary source for this information. In addition, USEPA's National Center for Environmental Assessment (NCEA) will be used as a source when necessary. In accordance with RAGS, a table will summarize toxicological data in the site-specific HHRAs in the form of RfDs and SFs obtained for COPCs identified in site media, as well uncertainty/modifying factors, target organs, and cancer classes (where available).

5.2 Evaluating Dermal Exposure and the Resulting Toxicity

In accordance with USEPA Region IV's *Supplemental Guidance to RAGS Bulletin 2*, dermal RfD values and SFs are derived from the corresponding oral values. As described in the supplemental guidance, the oral RfD is multiplied by an oral absorption efficiency factor (OAF), expressed as a decimal. The resulting dermal RfD is based on the absorbed dose. The RfD based on absorbed dose is the appropriate value with which to compare a dermal dose, because dermal doses are expressed as absorbed rather than administered (intake) doses. For the same reasons, a dermal SF is derived by dividing the oral SF by the OAF. The oral SF is divided rather than multiplied because SFs are expressed as reciprocal doses.

Appendix A of RAGS, Part A states that in the absence of specific data, an assumption of 5% oral absorption would be relatively conservative. *Supplemental Guidance to RAGS: Region IV Bulletin 2* indicates that in the absence of specific data, USEPA Region IV suggests an oral absorption factor of 80% for volatile organics, 50% for semivolatile organics, and 20% for inorganic chemicals. These percentages (or associated fractions) will be used in the site-specific HHRA

5.3 Toxicity Profiles for COPCs

In accordance with RAGS, toxicological summary paragraphs will be included in the body of the HHRA text for all COPCs. Most information for the profiles will be gleaned from IRIS and HEAST. Another source of information will be NCEA. Any additional references will be noted specifically in the text. The profiles will summarize adverse effects of COPCs and the amount associated with such effects.

6 Risk Characterization

Risk characterization combines the exposure assessment and toxicity assessment results to yield qualitative and quantitative expressions of risk and/or hazard for the exposed receptors. The quantitative component expresses the probability of developing cancer, or a threshold comparison

of the estimated dose with a reference dose for noncancer effects. These quantitative estimates are developed for individual chemicals, exposure pathways, transfer media, and source media, and for each receptor for all media to which one may be exposed. The qualitative component usually involves comparing COC concentrations in media with established criteria or standards for chemicals for which there are no corresponding toxicity values. The risk characterization helps guide risk-management decisions.

Generally, the risk characterization will follow the methodology prescribed by RAGS Part A, as modified by more recent information and supplemental guidance cited in the earlier sections of this memorandum. *The USEPA methods are designed to be health-protective and tend to overestimate risk rather than underestimate it. The risk results, therefore, are generally overly conservative, because risk characterization involves summing the overestimated risk estimates.*

6.1 Risk Characterization Methodology

Potential excess risks to humans following exposure to COPCs will be estimated using methods established by USEPA, when available. As discussed above, these methods are health-protective and are likely to overestimate risk. Risks from hazardous chemicals are calculated for either carcinogenic or noncarcinogenic effects. Some carcinogenic chemicals may also pose a noncarcinogenic hazard. The potential human health effects associated with chemicals that produce carcinogenic and other toxic effects will be characterized separately, as discussed below.

6.1.1 Carcinogenic Effects of Chemicals

The risk attributed to exposure to carcinogens is estimated as the probability of an individual developing cancer over a lifetime as a result of exposure to a potential carcinogen. In the low-dose range, which would be expected for most environmental exposures, cancer risk is estimated from the following linear equation (EPA, 1989a):

$$\text{ILCR} = (\text{CDI})(\text{SF})$$

where:

- ILCR = incremental lifetime excess cancer risk, a unitless expression of the probability of developing cancer, adjusted for reference incidence
- CDI = chronic daily intake, averaged over 70 years (mg/kg-day)
- SF = cancer slope factor (mg/kg-day)⁻¹

For a given pathway with simultaneous exposure of a receptor to several carcinogens, the following equation is used to sum cancer risks:

$$\text{Risk}_p = \text{ILCR}(\text{chem}_1) + \text{ILCR}(\text{chem}_2) + \dots + \text{ILCR}(\text{chem}_n)$$

where:

- Risk_p = total pathway risk of cancer incidence
- ILCR(chem_n) = incremental lifetime excess cancer risk for a specific chemical

Cancer risk for a given receptor across pathways and across media is summed in the same manner.

6.1.2 Noncarcinogenic Effects of Chemicals

The risks associated with the noncarcinogenic effects of chemicals are evaluated by comparing an exposure level or intake with a reference dose. The HQ, defined as the ratio of intake to RfD, is defined as (RAGS, Part A):

$$\text{HQ} = \text{CDI}/\text{RfD}$$

where:

- HQ = hazard quotient (unitless)
- CDI = intake of chemical (mg/kg-day)

RfD = reference dose (mg/kg-day)

Chemical noncarcinogenic effects are evaluated on a chronic basis, using chronic RfD values. An HQ of 1 indicates that the estimated intake equals the RfD. If the HQ is greater than unity, there may be a concern for potential adverse health effects.

In the case of simultaneous exposure of a receptor to several chemicals, an HI will be calculated as the sum of the HQs by:

$$HI = HQ_1 + HQ_2 + \dots HQ_i$$

where:

HI = Hazard Index (unitless)
HQ = Hazard Quotient (unitless)

Risk and hazard projections will be summarized in tabular format on a medium- and exposure pathway-specific basis in the HHRAs.

6.2 Surface Soil Pathways

Generally, the incidental ingestion and dermal contact pathways will be characterized for surface soil. Surface soil onsite will be evaluated under scenarios and exposure pathways outlined in the site-specific HHRAs.

6.3 Groundwater Pathways

Groundwater pathways will typically consist of ingestion and inhalation of volatilized chemicals in groundwater. The site-specific HHRAs will detail the pathways which will be addressed. Most groundwater pathways are not complete because municipal water supplies are used, and this will be discussed in the HHRAs.

6.4 COCs Identified

COCs will be identified based on cumulative (all pathway) risk and hazard projected for the sites. USEPA has established a generally acceptable risk range of $1E-4$ to $1E-6$, and an HI threshold of 1.0. Any COC that is carried through the risk assessment process and found to contribute to a scenario with an ILCR in excess of $1E-4$ or HI greater than 1 for any of the exposure scenarios evaluated in this risk assessment, and has an individual exposure pathway risk greater than $1E-6$ or exposure pathway HQ greater than 0.1, will be referred to as a COC. A table will present the COCs identified in site-specific HHRAs.

7 Risk Uncertainty

This section will discuss the uncertainty and variability inherent in the risk assessment process in addition to site-, medium-, and exposure pathway-specific influences. Overall, uncertainties associated with the initial stages of the risk assessment process become magnified when they are combined with other uncertainties. It is not possible to eliminate all uncertainties; however, recognizing the uncertainties is fundamental to understanding and subsequently using risk assessment results.

Where chronic RME estimates of risk/hazard indicated a significant threat (e.g., ILCR greater than $1E-4$) would be posed to human health, central tendency (CT) analysis may be performed. RME estimates are based on the upper bound (90th or 95th percentile) exposure assumptions, while CT estimates are based on the 50th percentile (mean or median) values. CT exposure scenarios are constructed consistent with standard CT exposure assumptions provided in *Superfund's Standard Default Exposure Factors for the Central Tendency and Reasonable Maximum Exposure-Draft* (USEPA, November 1993). CT exposure assumptions will be presented in the site-specific HHRAs, when applicable.

8 Risk Summary

Risk estimates will be presented and summarized in table form in the site-specific HHRAs.

9 Remedial Goal Options

RGOs are chemical concentrations computed to equate with specific risk and/or hazard goals that may be established for a particular site. As previously discussed, COCs are identified as any COPC that significantly contributes to a scenario of concern. RGOs will be calculated for each land use scenario with cumulative risk estimates greater than $1E-4$ or cumulative hazard indices greater than 1.0. Based on this method, COCs may be identified, requiring RGO calculation. Inclusion in the RGO table does not necessarily indicate that remedial action will be required to address a specific chemical. Instead, RGOs are provided to facilitate risk-management decisions.

In accordance with USEPA Supplemental RGO Guidance, RGOs will be calculated at $1E-4$, $1E-5$, and $1E-6$ risk levels for carcinogenic COCs and HI goals of 3, 1, and 0.1 for noncarcinogenic COCs. RGOs will be based on specific scenarios which will be identified in the site-specific HHRAs.

Chemical	Test Species	Test Type	Duration	Effect	Oral LD ₅₀ (mg/kg/BW)	LOAEL (mg/kgBW/day)	Reference
Inorganics							
Mercury (continued)	Prairie chicken	Single oral dose		Mortality	11.5		Eisler, 1987
	Chukar	Single oral dose		Mortality	26.9		Eisler, 1987
	Corturnix	Single oral dose		Mortality	11		Eisler, 1987
	Mallard	Oral	NR	Reproduction, behavior		0.064	USEPA, 1993
	Black duck	Oral (subchronic)	28 weeks	Reproduction inhibited		0.22 ^a	Eisler, 1987
	Fulvous whistling duck	Single oral dose		Mortality	37.8		Eisler, 1987
	Northern bobwhite	Single oral dose		Mortality	23.8		Eisler, 1987
	Bobwhite quail	Oral (acute)	5 days	Mortality	523		Hill et al., 1975
	Japanese quail	Single oral dose		Mortality	14.4		Eisler, 1987
	Gray partridge	Single oral dose		Mortality	17.6		Eisler, 1987
	Gray pheasant	Oral (subchronic)	30 days	Reduced reproductive ability		0.64	Eisler, 1987
	Ring-necked pheasant	Single oral dose		Mortality	11.5		Eisler, 1987
Nickel	Rat	Oral	NR	Reproductive effects		158	RTECS, 1994
		Single oral dose	NR	Mortality	67		ATSDR, 1987
Selenium	Rat	Oral	NR	Mortality	6,700		RTECS, 1993
		Oral	NR	Reproductive effects		134	RTECS, 1993
	Rat	Oral (subchronic)	3 months	Reduced hatchability		1.75	Eisler, 1985
Vanadium	Rat	Oral (acute)	5 days	Mortality	96		Hill and Camardese, 1986
Zinc	Rat	Single oral dose		Mortality	2,510		RTECS, 1993
	Rat	Oral (subchronic)	NR	Kidney toxicity		160	Llobet, et al., 1988

- Notes:**
LD50 = Dose resulting in 50% mortality in test population.
BW = Body weight.
LOAEL = Lowest Observed Adverse Effect Level.
NR = Not reported.
a = Converted to dose per kilogram body weight by multiplying by ingestion and dividing by body weight.
b = Estimated by applying a LOAEL-NOAEL ratio of 5 (Newell et al., 1987).
